#### Introduction

Body sensor networks composed of sensors and actuators can monitor the health of a patient.

This supports the assessment, monitoring and treatment in everyday environments in order to facilitate "health care in the community".

Such environment must be secure, autonomous, and continuously manage their own evolution and configuration changes. For example:

- Adapting the frequency of measurements in order to optimise power consumption.
- Changing the monitoring thresholds depending on the user's context.

We advocate the concept of self-managed cell (SMC) as a means of managing bodysensor networks. An SMC consists of hardware and software components which form an administrative domain capable of functioning autonomously.

#### The Self-Managed Cell (SMC) Discovers new devices and services, performs admission control The event bus provides the comprocedures to the cell and mainmunication infrastructure for the tains cell membership. components of an SMC. ### The *Ponder2* Policy Service

www.ponder2.net

Ponder2 combines a general purpose policy-based management system with a *domain service*, *obligation policy interpreter*, and a *com*mand interpreter.

- **Domain Service** provides a hierarchical structure for managed objects which represent sensors, actuators, other SMC devices, and remote SMCs
- **Obligation Policy Interpreter** implements Event-Condition-Action (ECA) rules
- Command Interpreter accepts commands in XML form via several communication interfaces. Commands invoke operations on managed objects including the domains and the policies themselves.

The *Ponder2* architecture comprises the domain structure, the triggering mechanism matching events to obligation policies and the execution invocation engine which is used to make calls to the objects inside the domain structure. event

The policy service has an event interface through which event notifications are received from the external event bus, an invocation interface through which external invocations are received and an action interface for invocations on external objects.

invocation

interf.

load(...)

Ponder2 can load all the code needed on demand. This includes factories for creating new object adapters (managed objects) for devices and remote services.

The policy service can use multiple communication protocols, such as UDP, Bluetooth, IEEE 802.15.4 and ZigBee.

policies (obligation & authorisation) bus managed object managed object (bsn) nurseMissionRef medical database glucose sensor blood pressure sensor heart rate sensor

Example of Domain Structure

An event factory implements the interface with an external event bus and encapsulates the protocols necessary to communicate with it.

The event factory is used to create new Event Types that issue subscriptions to the external content-based event bus. When an event matching the subscription occurs, the event factory is notified and it raises the corresponding event type in order to trigger the policies.

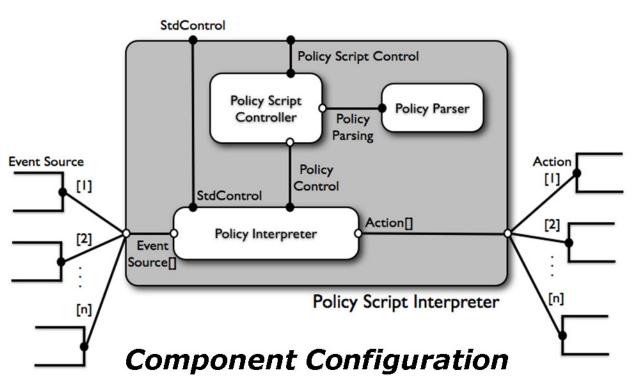

**Authorisation policies** — define what actions are permitted under given circumstances.

**Obligation policies** — define what actions to carry out when specific events occur if the specified condition is true.

The policy becomes active as soon as it is created. Policies can be enabled, disabled, and *removed* dynamically.

Ponder2 provides a complete management system for body-sensor networks, but it is not suitable for running on constrained body-sensors.

## The Tiny Policy Interpreter

Provides sensors with programmable local decision capability. It is a simplified policy interpreter running on TinyOS that can be deployed to BSN devices.

The **policy script con**troller is responsible for loading, adding and removing policies.

The **policy interpreter** is invoked to execute the actions according to the deployed obligation policies when event occurs.

Tiny policies are akin to obligation policies in *Ponder2*. They are specified as ECA rules. Events represent samples from sensors, conditions are represented as inclusive ranges. Event sources and actions are represented by NesC interfaces and they are pre-defined as arrays bound to the Tiny Policy Interpreter.

Tiny policy syntax is simpler and compact. Ponder2 policies can be translated into Tiny policies before deployment to the sensors.

#### **Policy Syntax**

policy = event condition "->" action

event = uint8 "?"

condition = equals\_condition

in\_range\_condition less\_than\_condition

greater\_than\_condition

between 5 and 9 inclusive, then perform action 1.

always\_condition

in\_range\_condition = "["min:uint32 ".." max:uint32"]"

always\_condition = "always" greater than condition = ">=" min:uint32

action = do\_action | set\_property\_action

do\_action = uint8 "!" action\_arg?

action\_arg = "(" uint32 ")"

For example, the policy 2? [5..9] -> 1! means that if event 2 fires with a parameter
