

• For example, **eg1**:

my @double my @twicelong	= map { \$_ * 2 } @orig; = map { \$_, \$_ * 2 } @orig;	# #	1,2,3,4 2,4,6,8 1,2,2,4,3,6,4,8 1=>2, 2=>4, 3=>6, 4=>8
my @even = gre	<pre>p { \$_ % 2 == 1 } @orig; my \$odd=join(',',@odd); p { \$_ % 2 == 0 } @orig; my \$even=join(',',@even); dd, even: \$even\n";</pre>		
my ©sq = gre my \$sq = join( print "sq: \$sq	',',@sq);	#	(1,4)

• Recall that **map** and **grep** are roughly:

map OP ARRAY is	grep OP ARRAY is
<pre>my @result = ();</pre>	my @result = ();
foreach (ARRAY)	foreach (ARRAY)
{	{
<pre>push @result, OP(\$_);</pre>	<pre>push @result, \$_ if OP(\$_);</pre>
}	}

-----

Ouncan White (CSG)

• For example: eg2 and eg3:

return \$n \* 2;

my \$coderef = \&double\_scalar;

my \$scalar = \$coderef->( 10 );

• Will produce 20 and (2,4,6) as output.

symbolised by TIME PASSES above.

print "scalar: \$scalar\n";

fun double\_scalar(\$n)

# TIME PASSES...

Perl Short Course: Seventh Session

 Note that a considerable amount of time may pass between taking the reference and calling the referenced function,

fun double\_array(@x)

# TIME PASSES

my \$coderef = \&double\_array;

my \$str = join(',',@array);
print "array: \$str\n";

my @array = \$coderef->( 1, 2, 3 );

return map { \$\_ \* 2 } @x;

{

• Most programmers come to Perl from imperative/OO languages

```
• Can generalise this to eg4:
     fun double_scalar($n)
            return $n * 2.
     }
     fun double_array(@x)
     Ł
            return map { $_ * 2 } @x;
     }
     fun apply( $coderef, @args )
            return $coderef->( @args );
     }
     my $scalar = apply( \&double_scalar, 10 );
     print "scalar: $scalar\n";
     my @array = apply( \&double_array, 1, 2, 3 );
     my $str = join(',',@array);
     print "array: $str\n";
```

- The results are the same as before.
- You might wonder whether you need to name little helper functions like double\_scalar if the only use of them is to make a coderef via \&double\_scalar.

```
Duncan White (CSG)
```

7 / 22

nal Programming Techniques Data-Driven Programming: Coderefs in Data Structures

Coderefs can be built into data structures such as:

```
my %op = (
        '+' => fun ($x,$y) { $x + $y },
        '-' => fun ($x,$y) { $x - $y },
        '*' => fun ($x,$y) { $x * $y },
        '/' => fun ($x,$y) { $x / $y },
);
```

• Then a particular coderef can be invoked as follows:

```
my $operator = "*"; my $x = 10; my $y = 20;
my $value = $op{$operator}->( $x, $y );
```

• We can use the above technique to build a simple *Reverse Polish* 

# *Notation (RPN)* evaluator:

```
fun eval_rpn(@atom)
                                          # each atom: operator or number
   mv @stack:
                                          # evaluation stack
    foreach my $atom (@atom)
       # number?
           push @stack, $atom;
       } else
                                         # operator?
           die "eval_rpn: bad atom $atom\n" unless exists $op{$atom};
           my $y = pop @stack; my $x = pop @stack;
           push @stack, $op{$atom}->( $x, $y );
       }
   }
   return pop @stack:
3
                                                                      December 2012
                          Perl Short Course: Seventh Session
```

#### ing Techniques Functions as First Order Citizens

• You'd be right to wonder! Use *anonymous coderefs* as in **eg5**:

```
fun apply( $coderef, @args )
        return $coderef->( @args );
3
my scalar = apply(fun ($x) { return $x * 2 }, 10 );
```

print "scalar: \$scalar\n";

my @array = apply( fun (@x) { return map { \$\_ \* 2 } @x }, 1, 2, 3 ); my \$str = join(',',@array); print "array: \$str\n";

• If we add a prototype to apply via:

fun apply(\$coderef,@args) :(&@) # or sub (&@) { my(\$coderef,@args)=@\_;.. (Here, & tells Perl the given argument *must be a coderef*.)

• Then add the following inside apply:

local \$\_ = \$args[0];

(local saves the old value of the global \$\_, before setting it to the given value, the new value persists until apply returns when the old value is restored.)

• Now we can write map like code using \$\_:

my \$scalar = apply { \$\_ \* 2 } 10;

Duncan White (CSG)

December 2012 6 / 22

### ing Techniques Data-Driven Programming: Coderefs in Data Structures

• The above RPN evaluator, with some more error checking and example calls such as:

Perl Short Course: Seventh Session

my \$n = eval\_rpn( qw(1 2 3 \* + 4 - 5 \*) );

is eg6. Try it out.

- This technique is often called *data-driven* or *table-driven* programming, very easy to extend by modifying the table.
- For example, add the following operators (giving eg7):

```
my %op = (
        ,%,
                => fun ($x,$y) { $x % $y },
        , ~ ,
                => fun ($x,$y) { $x ** $y },
        ·>'
                => fun ($x,$y) { $x > $y },
        'swap' => fun ($x,$y) { ($y, $x) },
);
```

- % and ^ are conventional binary operators, but note that swap takes 2 inputs and produces 2 outputs - the same two, swapped!
- This works because whatever the operator returns, whether one or many results, is pushed onto the stack.

- To vary the number of inputs each operator takes, change the data structure and code slightly (giving **eg8**).
- First, change the data structure:

• Here, each hash value is changed from a coderef to a *reference to* a 2-element list, i.e. a 2-tuple, of the form:

[ no\_of\_args, code\_ref ].

• So each existing binary operator op => function pair becomes:

op => [ 2, function ]

But now we can add unary and trinary ops as follows:

```
my %op = (
    ...
    'neg' => [ 1, fun ($x) { - $x } ],
    'sqrt' => [ 1, fun ($x) { sqrt( $x ) }],
    'ifelse' => [ 3, fun ($x,$y,$z) { $x ? $y : $z }],
);
uncan White (CSG) Perl Short Course: Seventh Session December 2012 9 / 22
```

### Functional Programming Techniques Functions returning Functions: Closures and Iterators

- So far, we've only seen passing coderefs into functions.
- However, you can write a **function factory** which *constructs and returns a coderef.* For example:

```
fun timesn($n)
{
        return fun ($x) { return $n * $x };
}
```

- timesn(N) delivers you a newly minted coderef which, when it is later called with a single argument, multiplies it by N.
- For example (**eg9**):

```
my $doubler = timesn(2);
my $d = $doubler->(10);  # 20
my $tripler = timesn(3);
my $t = $tripler->(10);  # 30
print "d=$d, t=$t\n";
```

• Subtlety: in C, a function pointer is simply a machine address. In Perl, a coderef is a **closure:** a *machine address plus a private environment*. In this case, each timesn() call has a different local variable \$n which the coderef must remember.

• The operator invocation code changes to:

- I rather like the args = reverse map {pop} 1..n line:-)
- This now allows a call such as:

my  $n = eval_rpn(qw(7 5 * 4 8 * > 1 neg 2 neg ifelse));$ 

• This is equivalent to the more normal expression:

if(  $7{\ast}5$  >  $4{\ast}8$  ) –1 else –2

- Which, because 35 > 32, gives -1.
- Change the 5 to a 4, this (because  $28 \le 32$ ) gives -2.
- One could make further extensions to this RPN calculator, in particular variables could be added easily enough (store them in a hash, add get and set operators). But we must move on.

```
Duncan White (CSG)
```

Perl Short Course: Seventh Session

December 2012 10 / 22

### Functional Programming Techniques Functions returning Functions: Closures and Iterators

 Objection 1: the previous example only used one coderef at a time. Replace the calls as follows (eg10):

- Here, we select either the doubler or the tripler based on dynamic input the doubler if the current command line argument is odd, else the tripler. So eg10 1 2 3 4 generates 2 6 6 12.
- Objection 2: \$n was a known (constant) value when the coderef was built. Did Perl rewrite it as a constant?
- We can disprove this idea a coderef can change it's environment!

fun makecounter(\$n)
{
 return fun { return \$n++ };
}

#### Functional Programming Techniques Functions returning Functions: Closures and Iterators

```
• To use makecounter() write (eg11):

my $c1 = makecounter( 10 );
```

```
my $v;
$v = $c1->(); print "c1: $v\n";
$v = $c1->(); print "c1: $v\n";
$v = $c1->(); print "c1: $v\n";
```

- Every time \$c1 is called, it retrieves the current value of it's private variable \$n, increments it for next time, and returns the previous value. So eg11 delivers 10 11 12.
- This is a special type of closure called an *iterator*. Calling an iterator to deliver the next value is called *kicking the iterator*.
- Objection 3: anyone can juggle one ball. Can you have more than one counter? Yes! **eg12** shows this:

# Functional Programming Techniques Functions returning Functions: Closures and Iterators

```
• It's easy to define map and grep for iterators:
    # $it2 = map_i( $op, $it ): Equivalent of map for iterators.
           Given two coderefs ($op, an operator, and $it, an iterator),
           return a new iterator $it2 which applies $op to each value
           returned by the inner iterator $it.
    fun map_i( $op, $it ) :(&$)
            return fun {
                   my $v = $it->();
                   return undef unless defined $v;
                   local $_ = $v;
                   return $op->($v):
           };
    3
• Now, we can write (eg15):
    mv $lim = shift @ARGV || 10:
    my $scale = shift @ARGV || 2;
    my $c = map_i { $_ * $scale } upto( 1, $lim );
    while( my $n = $c->() ) { print "$n,"; }
    print "\n";
• When run with lim=10, scale=3, this produces:
   3,6,9,12,15,18,21,24,27,30,
• grep_i(sop, sit) is not much more complicated, eg16 shows it
   (omitted here).
```

- So far, our iterators have generated infinite sequences. But an iterator can terminate when it finishes iterating (like each).
- Easy to do, return a sentinel value to inform us that the iterator has finished. Most obvious value: undef. For example:

```
fun upto( $n, $max )
{
        return fun {
            return undef if $n > $max;
            return $n++;
        };
}
```

• You might call this with code like (eg13):

- $\bullet\,$  When run, this counts from 1 to 10 and then stops. Multiple
- counters work fine (because n and \$max form the closure environment), **eg14** shows an example (omitted here).

```
Duncan White (CSG)
```

Perl Short Course: Seventh Session

```
December 2012 14 / 22
```

#### Functional Programming Techniques Functions returning Functions: Currying

- A hard-core functional programming feature is **Currying**: the ability to *partially call a function* to provide (say) a 3-argument function with it's first argument and deliver a 2-argument function.
- Simple to do:

```
fun curry( $func, $firstarg )
{
    return fun {
        return $func->( $firstarg, @_ );
    };
}
```

• You might call this with code like (eg17):

fun add(\$a,\$b) { return \$a + \$b };

```
my $plus4 = curry( \&add, 4 );
my $x = $plus4->(10);
print "x=$x\n";
```

- # an "add 4 to my arg" func
  # x=10+4 i.e. 14
- As expected, the \$plus4 function acts exactly as an *add 4 to my* single argument function, delivering 14 as the result.

13 / 22

- One of the coolest features of functional programming languages is **lazy evaluation** the ability to handle very large or even infinite data structures, evaluating only on demand.
- It's surprisingly easy to add laziness in Perl:
- Let's extend last lecture's linked List module to work with *lazy linked lists* (sometimes known as *streams*).
- Only one design change is needed: allow a list tail to *either* be an ordinary *nil-or-cons* list *or a coderef* a **promise** to deliver the next part of the list (whether empty or nonempty) on demand.
- When *slist->headtail* splits a node into head *sh* and tail *st*, we'll need to detect whether *st* is a promise (a coderef), via *ref(st) eq "CODE"*. If *st* is a promise, we must **force the promise** invoking the promise function, which will deliver a real list (empty or nonempty) which is the real tail:

```
my( $h, $t ) = @$self;
$t = $t->() if ref($t) eq "CODE";  # FORCE A PROMISE
return ( $h, $t );
```

```
Duncan White (CSG)
```

Perl Short Course: Seventh Session December 2012

```
Functional Programming Techniques Lazy Evaluation
```

- Then, give it a proper lazy list (eg19) by adding a fun {} (or sub {} on older Perls) coderef wrapper on the list\_upto(\$min+1, \$max) call: return List->cons( \$min, fun { list\_upto(\$min+1, \$max) } );
- Without this, it was a conventional recursive function to generate a list. By *delaying the recursive call* until it's actually needed, we make it lazy.
- In this case, despite producing identical output, the lazy version never computes or stores elements 108..200.
- We can easily define *map-like* and *grep-like* operators taking and delivering lists. Here's map\_l(\$op, \$list):

```
return List->nil() if $list->isnil;
my( $h, $t ) = $list->headtail;
local $_ = $h; # set localised $_ for op
return List->cons( $op->($h), fun { map_l( $op, $t ); } );
```

• Note that we've not made this a method, as we prefer to keep the map-like syntax rather than swap the arguments around in order to have the list (object) as the first argument. Instead we've given it a non clashing name and exported it.

- Concern: a lazy list might be finite, or infinite. Given an infinite list \$inflist, we have a fundamental problem: \$inflist->len, \$inflist->rev
  and \$inflist->append(\$second\_list) will never terminate. This can't be
  solved it's inevitable!
- Fortunately, we have already engineered the concept of "show only the first N elements" into \$inflist->as\_string() so that's ok.
- Perhaps we should set the system-wide limit to a reasonably large value, rather than leaving it zero (meaning unlimited):

our \$as\_string\_limit = 40;

• Having modified and syntax checked List.pm, check that it still works with lists with no promises - i.e. non lazy lists (eg18):

```
use List;
$List::as_string_limit = 8;
# list_upto: return a non-lazy list of numbers between $min and $max
fun list_upto( $min, $max )
{
    return List->nil() if $min > $max;
    return List->cons( $min, list_upto($min+1, $max) );
}
my $list = list_upto( 100, 200 );
print "first few elements of upto(100,200) List: $list\n";
can White (CSC) Perl Short Course: Seventh Session December 2012 18 / 22
```

#### Functional Programming Techniques Lazy Evaluation

# • grep\_1(\$op, \$list) IS:

• Using map\_1(%op, \$list) and grep\_1(%op, \$list), we can write rather pretty mathematical-style code. For example, start with an infinite list of odd numbers (eg20):

```
use List;
$List::as_string_limit = 8;
# $list = stepup( $n, $step ) - return an infinite list n, n+step, n+2*step...
fun stepup( $n, $step )
{
        return List->cons( $n, fun { stepup($n+$step,$step); } );
}
my $odds = stepup( 1, 2 );
print "first few odds: $odds\n";
```

### Functional Programming Techniques Lazy Evaluation

# • Which produces:

first few odds: [1,3,5,7,9,11,13,15,17,19...]

 Then generate an infinite list of even numbers by: my \$evens = map\_1 {\$\_+ 1} \$odds; print "first few evens: \$evens\n";

## Unsurprisingly, this produces:

first few evens: [2,4,6,8,10,12,14,16,18,20...]

• Then select only even numbers greater than 7:

my \$evengt7 = grep\_1 {\$\_ > 7} \$evens;

# Which produces:

first few even gt7: [8,10,12,14,16,18,20,22,24,26...]

 Finally, we can select the subset that are exact squares: my \$squares = grep\_1 { my \$r = int(sqrt(\$\_)); \$r\*\$r == \$\_} evengt7;

# Which produces:

first few even perfect squares > 7: [16,36,64,100,144,196,256,324,400,484...]

• Of course, this sequence of calls could be written as (eg20a):

my \$evensgt7 = stepup( 8, 2 ); my \$squares = grep\_1 { my \$r = int(sqrt(\$\_)); \$r\*\$r == \$\_ } \$evensgt7;

Duncan White (CSG)

Perl Short Course: Seventh Session December 2012

21 / 22

#### Functional Programming Techniques Lazy Evaluation

 We can even provide a merge\_1( \$cmp, \$list1, \$list2 ) list operator to merge two sorted lists using a sort-like comparator, and using it (eg21):

**g21**).

- my \$odds = stepup( 1, 2 );
  my \$evens = stepup( 2, 2 );
- my \$all = merge\_1 { \$a <=> \$b } \$odds, \$evens;

What do you get it by merging odd and even integers? All integers!

# • A better example might be (eg22):

```
# $list = power( $n, $p ) - return an infinite list n, n*p, n*p^2..
     fun power($n, $p)
     ſ
            return List->cons( $n, fun { power($n*$p,$p); } );
     3
     my twos = power(1, 2);
                                          # powers of 2
     my $threes = power(1, 3);
                                          # powers of 3
     my $fives = power( 1, 5 );
                                          # powers of 5
     my $m23 = merge_1 { $a <=> $b } $twos, $threes;
     mv $m235 = merge 1 { $a <=> $b} $m23. $fives:
     my $all = grep_l { $_ > 1 } $m235;
     print "first few merged values: $all\n";
• Here's a use for currying the comparator into merge_1 (eg22a):
```

my \$merge\_numeric = curry( \&merge\_l, sub { \$a <=> \$b } ); my \$m235 = \$merge\_numeric->( \$merge\_numeric->( \$twos, \$threes ), \$fives ); my \$all = grep\_l { \$\_ > 1 } \$m235;

Duncan White (CSG)

Perl Short Course: Seventh Session December 2012
