Lecture 4

Manipulation of Three Dimensional Objects

Graphics Lecture 4: Slide 1

The Concept of a Halfspace

Graphics Lecture 4: Slide 2

The same idea extends to three dimensions

Graphics Lecture 4: Slide 3

Convex Objects

We can use the halfspace property for a number of algorithms for manipulating graphics scenes.

We will consider first convex objects, and the first algorithm is to determine whether an object is convex or not.

Graphics Lecture 4: Slide 4

Two Definitions of Convex

1. A line joining any two points on the boundary lies inside the object.
2. The object is the intersection of planar halfspaces.

Graphics Lecture 4: Slide 5

Algorithm for determining if an object is convex

```
convex = true
for each face of the object
{ find the plane equation of the face  $f(x,y,z) = 0$ 
  choose one object point  $(x_i, y_i, z_i)$  not on the face
  and find  $sign(f(x_i, y_i, z_i))$ 
  for all other points of the object
  { if  $(sign(f(x_j, y_j, z_j))) \neq sign(f(x_i, y_i, z_i))$ 
    then convex = false
  }
}
```

Graphics Lecture 4: Slide 6

Testing for Convex

Graphics Lecture 4: Slide 7

Testing for Containment

A frequently encountered problem is to determine whether a point is inside an object or not.

We need this for clipping algorithms

Graphics Lecture 4: Slide 8

Algorithm for Containment

let the test point be $[x_t, y_t, z_t]$

contained = *true*

for each face of the object

{ find the plane equation of the face $f(x, y, z) = 0$
choose one object point (x_i, y_i, z_i) not on the face
and find *sign*($f(x_i, y_i, z_i)$)

if (*sign*($f(x_t, y_t, z_t)$) not = *sign*($f(x_i, y_i, z_i)$))
then contained = *false*

}

Graphics Lecture 4: Slide 9

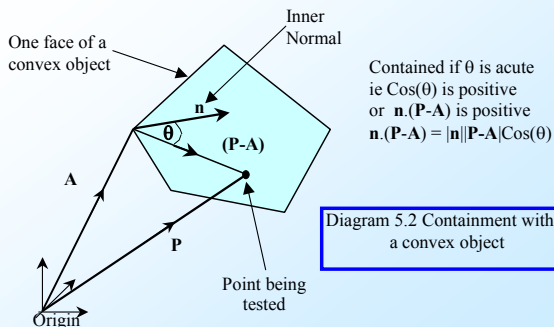

Vector formulation

The same test can be expressed in vector form.

This avoids the need to calculate the Cartesian equation of the plane, if, in our data base we store the normal \mathbf{n} vector to each face of our object.

Graphics Lecture 4: Slide 10

Vector test for containment

Graphics Lecture 4: Slide 11

Normal vector to a face

The vector formulation does not require us to find the plane equation of a face, but it does require us to find a normal vector to the plane.

(same thing really since for plane $ax + by + cz + d = 0$ a normal vector is $[a, b, c]$)

Graphics Lecture 4: Slide 12

Finding a normal vector

The normal vector can be found from the cross product of two vectors on the plane, say two edge vectors

Graphics Lecture 4: Slide 13

But which normal vector points inwards?

Graphics Lecture 4: Slide 14

Checking the normal direction

Graphics Lecture 4: Slide 15

Problem Break

A face of a convex object lies in the plane $3x+5y+7z+1=0$ and a vertex is $\{-1,-1,1\}$
The normal vector is therefore $\mathbf{n} = \{3,5,7\}$

1. If another vertex of the object is $\{1,1,1\}$ determine whether \mathbf{n} is an inner or outer surface normal.
(see fig 6.4)

2. Determine whether the point $\{1,0,-1\}$ is on the inside or the outside of the face.

Graphics Lecture 4: Slide 16

Solution 1

$$\mathbf{P}-\mathbf{A} = \{1,1,1\} - \{-1,-1,1\} \\ = \{2,2,0\}$$

$$\mathbf{n} \cdot (\mathbf{P}-\mathbf{A}) = 6 + 10 = 16$$

$\mathbf{n} \cdot (\mathbf{P}-\mathbf{A})$ is positive,

θ is acute

\mathbf{n} is an inner normal

Graphics Lecture 4: Slide 17

Solution 2

Method 1:

The plane has equation $3x+5y+7z+1=0$

ie $f(x,y,z) = 3x+5y+7z+1$

For the internal point $\{1,1,1\}$ $f(1,1,1) = 16$

For the test point $\{1,0,-1\}$ $f(1,0,-1) = -3$

The signs are different, so the test point is on the outside

Graphics Lecture 4: Slide 18

Solution 3

Method 2:

The inner surface normal is $\mathbf{n} = \{3,5,7\}$

for the test point $\mathbf{P} = \{1,0,-1\}$ and vertex $\mathbf{A} = \{-1,-1,1\}$

$\mathbf{P}-\mathbf{A} = \{2,1,-2\}$

$\mathbf{n} \cdot (\mathbf{P}-\mathbf{A}) = -3$

Thus the angle to the normal is > 90

The point is on the outside

Clipping

Containment is an important property used in clipping algorithms.

Clipping is used to remove unwanted parts of a graphics scene before drawing.

It can be applied in computer aided design, and graphics scene design.

Clipping a line to a convex polyhedron

Clipping algorithm

The algorithm checks the line against every face of the convex polyhedron.

It determines whether the end points of the line are on the inside or the outside of the face

This can be done by the halfspace or the dot product with the inner normal as before.

Case 1: Both P_1 and P_2 are on the outside

The line is completely clipped (no part of it is inside the polyhedron)

The algorithm terminates

Case 2: Both P_1 and P_2 are on the inside

There is no new information.

If there are more faces to test the algorithm continues to the next face.

Otherwise the line is completely inside the volume.

Case 3: P_1 is outside and P_2 is inside

Compute the intersection between the line and plane.
for any vector \mathbf{p} lying on the plane $\mathbf{n} \cdot \mathbf{p} = 0$
let the intersection point be $\mu_i \mathbf{P}_2 + (1 - \mu_i) \mathbf{P}_1$
if A is a vertex of the object a vector on the plane is
 $\mu_i \mathbf{P}_2 + (1 - \mu_i) \mathbf{P}_1 - \mathbf{A}$
thus $\mathbf{n} \cdot (\mu_i \mathbf{P}_2 + (1 - \mu_i) \mathbf{P}_1 - \mathbf{A}) = 0$
we can solve this for μ_i and hence find the point of
intersection
Replace \mathbf{P}_1 with the intersection

Graphics Lecture 4: Slide 25

Case 3: P_2 is outside and P_1 is inside

This is equivalent to case 3 with P_1 and P_2 exchanged

Graphics Lecture 4: Slide 26

Clipping to a viewing volume

The visible parts of a graphics scene are bounded by six planes.
For efficient computation all invisible parts should be clipped

Graphics Lecture 4: Slide 27

Concave Objects

Containment and clipping can also be carried out with
concave objects.

Most algorithms are based on the ray containment
test.

Graphics Lecture 4: Slide 28

The Ray test in two dimensions

Find all intersections between the ray and the polygon edges.
If the number of intersections is odd the point is contained

Graphics Lecture 4: Slide 29

Calculating intersections with rays

Rays have equivalent equations to lines, but go in
only one direction. For test point T a ray is defined as

$$\mathbf{R} = \mathbf{T} + \mu \mathbf{d} \quad \mu > 0$$

We choose a simple to compute direction eg

$$\mathbf{d} = [1, 0, 0]$$

Graphics Lecture 4: Slide 30

Valid Intersections

Graphics Lecture 4: Slide 31

Extending the ray test to 3D

A ray is projected in any direction.

If the number of intersections with the object is odd, then the test point is inside

Graphics Lecture 4: Slide 32

3D Ray test

There are two stages:

1. Compute the intersection of the ray with the plane of each face.
2. If the intersection is in the positive part of the ray ($\mu > 0$) check whether the intersection point is contained in the face.

Graphics Lecture 4: Slide 33

The plane of a face

Unfortunately the plane of a face does not in general line up with the Cartesian axes, so the second part is not a two dimensional problem.

However, containment is invariant under orthographic projection, so it can be simply reduced to two dimensions.

Graphics Lecture 4: Slide 34

Clipping to concave volumes

Find every intersection of the line to be clipped with the volume.

This divides the line into one or more segments.

Test a point on the first segment for containment

Adjacent segments will be alternately inside and out.

Graphics Lecture 4: Slide 35

Splitting a volume into convex parts

If all the object vertices lie on one side of the plane of a face, we proceed to the next face

Graphics Lecture 4: Slide 36

If the plane of a face cuts the object:

Split the Object
