On the Priorean temporal logic with ‘around now’
over the real line

Ian Hodkinson*

October 14, 2013

Abstract

We consider the temporal language with the Priorean operators $G$ and $H$ expressing that a formula is true at all future times and all past times, plus an operator $\Box$ expressing that a formula is true throughout some open interval containing the evaluation time (i.e., it is true ‘around now’). We show that the logic of time based on the real numbers in this language is finitely axiomatisable, answering an implicit question of Shehtman (1993). We also show that the logic has PSPACE-complete complexity, but is not Kripke complete and has no strongly complete axiomatisation.

Keywords Weak completeness, finite axiomatisation, filtration, lexicographic sum, Kripke-incompleteness.

1 Introduction

Modal formulas can be given semantics in models based on topological spaces. In a topological model, the formula $\Box \varphi$ is true at a point if $\varphi$ is true throughout some open neighbourhood of that point. So the set of points satisfying $\Box \varphi$ is the interior of the set of points satisfying $\varphi$. Topological semantics predates Kripke semantics and was first considered by McKinsey and Tarski [20], who proved that the logic of any separable dense-in-itself metric space, such as the rationals ($\mathbb{Q}$) and reals ($\mathbb{R}$) with the usual metric, is $S_4$. Interest in this theorem is undergoing a renaissance and several new proofs have recently appeared [21, 22, 2, 1, 17, 10], either for $\mathbb{R}$ alone or for the general case. The assumption of separability was removed in [24]. The theorem was extended by Kremer [13, 12] to a strong completeness result for any dense-in-itself metric space (for countable languages).

Additional connectives have also been considered. Shehtman added the universal modality $\forall$: a formula $\forall \varphi$ is true at an arbitrary point of a topological model if $\varphi$ is true at every point. He showed in [29] that the logic of any connected separable

---

*I thank Nick Bezhanishvili and Alberto Gatto for several useful discussions. I also thank the referees for finding some errors and making many suggestions on presentation, which led to major revision.
dense-in-itself metric space, such as $\mathbb{R}$, is S4UC, with S4 axioms for $\Box$, the usual axioms U for $\forall$, and a connectedness axiom C: $\forall(\Box p \lor \Box \neg p) \rightarrow \forall p \lor \forall \neg p$.

Kudinov added the difference operator $[\neq]$: a formula $[\neq]\varphi$ is true at a point if $\varphi$ is true at every other point. The difference operator is more expressive than $\forall$. In the language with $\Box$, $[\neq]$, Kudinov axiomatised the logic of all topological spaces, all dense-in-themselves topological spaces, and any zero-dimensional dense-in-itself metric space [14]. He also axiomatised the logic of $\mathbb{R}^n$ for $n \geq 2$ (unpublished), but proved [15] that the logic of $\mathbb{R}$ is not finitely axiomatisable, and not even axiomatisable by formulas using finitely many variables in total.

In [28], Shehtman shifted attention to temporal logic by adding the Priorian temporal connectives $G$ and $H$ to the original $\Box$. This language is given semantics in ordered topological models. An ordered topological model is a topological model whose topology is the interval topology arising from an irreflexive linear order $<$ on the set of points. Examples include models based on $\mathbb{Q}$ and $\mathbb{R}$ with their usual orderings and topologies. Such models can be viewed temporally. We can regard the points as times and the order $<$ as the earlier-later relation, so that $x < y$ denotes that $x$ is in the past of $y$ and $y$ in the future of $x$. A formula $G\varphi$ is true at a point or time $x$ in such a model if $\varphi$ is true at all future times — all $y$ satisfying $x < y$. A formula $H\varphi$ is true at $x$ if $\varphi$ is true at all past times $y < x$. Together, the connectives $G, H$ are even more expressive than $[\neq]$. In the temporal context, $\Box \varphi$ can still be read topologically, but it also has a reasonable temporal reading as ‘$\varphi$ is true around now’, and this view was promulgated by Scott. In [28], Shehtman gave a finite axiomatisation of the logic of $\mathbb{Q}$ in this language, observed that the logic of $\mathbb{R}$ in the same language is decidable and hence recursively axiomatisable, and implicitly posed [28, p.256] the problem of axiomatising it explicitly. Although the area of topological semantics of modal logic has recently attracted a good deal of attention, this problem has remained open.

Although it has no topological $\Box$-modality, the very expressive temporal language with $U$ and $S$ (Until and Since) is worth mentioning here. A formula $U(\varphi, \psi)$ is true at a time point $x$ if there is a point $y > x$ at which $\varphi$ is true and such that $\psi$ is true at every $z$ with $x < z < y$ — informally, $\psi$ is true until $\varphi$ becomes true. The meaning of $S$ is obtained by swapping $<$ with $>$. The connectives $U$ and $S$ were introduced by Kamp [11] and they can easily express all the connectives we have considered so far. Indeed, over $\mathbb{R}$, they can express every connective whose meaning is definable in first-order logic [11]. Reynolds gave a finite axiomatisation of the logic of $\mathbb{R}$ with $U, S$ in [25], and showed the logic to be PSPACE-complete in [26].

In the current paper we consider Shehtman’s temporal language with $G, H$, and $\Box$, interpreted over $\mathbb{R}$. We answer Shehtman’s implicit question [28] by showing that the logic of $\mathbb{R}$ in this language is finitely axiomatisable. Given Kudinov’s result, this is perhaps surprising, but given Reynolds’s, it is less so. It suggests that $G, H$, and $\Box$ are in some sense closer to Until and Since over $\mathbb{R}$ than to $[\neq]$ and $\Box$. We obtain only ‘weak completeness’, and we show that no strong completeness result can be proven. We also show that the logic is not Kripke complete. As we said, Shehtman observed in [28] that it is decidable, and we show here that it is PSPACE-complete.

Our axiom system is similar to the one for $\mathbb{Q}$ given by Shehtman in [28] — the
only difference is that we include an additional connectedness axiom $F(p \land Fq) \land F(\neg p \land Fq) \rightarrow F(\Diamond p \land \neg q \land Fq)$, where $F\varphi$ abbreviates $\neg G \neg \varphi$. Our completeness proof starts in the same way as well, by a certain filtration of the canonical model.

We then apply selective filtration and a closure technique designed to give a well behaved finite Kripke model, which we employ as a template to construct a model over $\mathbb{R}$, using lexicographic sums.

**Layout of paper.** Section 2 contains the basic definitions, and section 3 the system of axioms and inference rules for the logic of $\mathbb{R}$ in the language with $G$, $H$, and $\Box$. In section 4 we prove that the logic has no strong axiomatisation and is not Kripke complete, but is (decidable and) PSPACE-complete (decidability was known to Shehtman). Section 5 outlines the coming completeness proof. Section 6 builds the well behaved finite Kripke model referred to above, and section 7 constructs from it a model over $\mathbb{R}$. We conclude in section 8 with some open problems.

Throughout, we use $\mathbb{N}$, $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$ to denote the ordered sets of natural numbers, integers, rationals, and real numbers (respectively).

## 2 Generalities

Here, we lay down the syntax and semantics of our logic, and define some basic terms.

### 2.1 Syntax

Let $PV$ be a fixed countably infinite set of propositional atoms. We write $p, q, r, \ldots$ for atoms. We define the language $L$ to consist of the following formulas:

1. $\top$ is a formula.
2. Every $p \in PV$ is a formula.
3. If $\varphi, \psi$ are formulas then so are $\neg \varphi$, $\varphi \land \psi$, $G\varphi$, $H\varphi$, and $\Box \varphi$.

The *mirror image* of a formula $\varphi$ is the formula obtained by replacing every $G$ in $\varphi$ by $H$, and every $H$ in $\varphi$ by $G$. As abbreviations we let $\bot = \neg \top$, $\varphi \lor \psi = \neg (\neg \varphi \land \neg \psi)$, $\varphi \rightarrow \psi = (\varphi \rightarrow \psi) \land (\psi \rightarrow \varphi)$, $F\varphi = \neg G \neg \varphi$, $P\varphi = \neg H \neg \varphi$, and $\Diamond \varphi = \neg \Box \neg \varphi$.

### 2.2 Semantics over $\mathbb{R}$

We define semantics for $L$-formulas over $\mathbb{R}$ as follows. Let $h : PV \rightarrow \wp(\mathbb{R})$ be an assignment to atoms (where $\wp$ denotes power-set). The pair $(\mathbb{R}, h)$ is then called a *model over $\mathbb{R}$*. For each $x \in \mathbb{R}$ and formula $\varphi$ we define $(\mathbb{R}, h), x \models \varphi$ by induction:

1. $(\mathbb{R}, h), x \models \top$,
2. $(\mathbb{R}, h), x \models p$ iff $x \in h(p)$, for $p \in PV$,
3. $(\mathbb{R}, h), x \models \neg \varphi$ iff $(\mathbb{R}, h), x \not\models \varphi$,
4. $(\mathbb{R}, h), x \models \varphi \land \psi$ iff $(\mathbb{R}, h), x \models \varphi$ and $(\mathbb{R}, h), x \models \psi$,
5. \((\mathbb{R}, h), x \models G \varphi\) iff \((\mathbb{R}, h), y \models \varphi\) for all \(y \in \mathbb{R}\) with \(y > x\),
6. \((\mathbb{R}, h), x \models H \varphi\) iff \((\mathbb{R}, h), y \models \varphi\) for all \(y \in \mathbb{R}\) with \(y < x\),
7. \((\mathbb{R}, h), x \models \Box \varphi\) iff there exist \(y, z \in \mathbb{R}\) with \(y < x < z\) and \((\mathbb{R}, h), t \models \varphi\) for all \(t \in \mathbb{R}\) with \(y < t < z\).

A model \((\mathbb{R}, h)\) over \(\mathbb{R}\) is said to satisfy a formula \(\varphi\) if there is some \(x \in \mathbb{R}\) with \((\mathbb{R}, h), x \models \varphi\). We say that \(\varphi\) is satisfiable over \(\mathbb{R}\) if some model over \(\mathbb{R}\) satisfies it, and \(\varphi\) is valid over \(\mathbb{R}\) if \(\neg \varphi\) is not satisfiable over \(\mathbb{R}\). A set \(\Sigma\) of \(L\)-formulas is said to be satisfiable over \(\mathbb{R}\) if there exist an assignment \(h : PV \to \varphi(\mathbb{R})\) and \(x \in \mathbb{R}\) with \((\mathbb{R}, h), x \models \varphi\) for every \(\varphi \in \Sigma\).

The \(L\)-logic of \(\mathbb{R}\) is the set of all \(L\)-formulas that are valid over \(\mathbb{R}\).

### 2.3 Kripke semantics

Formulas have an alternative Kripke semantics. A binary relation on a set \(W\) is a subset \(R\) of \(W \times W\). For \(w, u \in W\), we may write any of \(Rwu, wRu, R(w, u)\) to indicate that \((w, u) \in R\).

A Kripke frame (for \(L\)) is a triple \((W, \sqsubseteq, R)\), where \(W\) is a non-empty set and \(\sqsubseteq, R\) are binary relations on \(W\), associated with \(G, \Box\), respectively. Occasionally we consider frames of the form \((W, R)\) as well.

The choice of the symbol \(\sqsubseteq\) for the ‘temporal’ relation may be controversial, so we will spend a little space justifying it. After all, in [28], Shehtman used the symbol \(S\). We find \(\Box\) convenient because it gives rise to readily understood symbols \(\sqsubseteq, \sqsupseteq, \sqsubset\) for various derived relations, and also because the temporal relations in the main proof will always be transitive, a property that is suggested by the symbol \(\sqsubseteq\). However, we stress at the outset that in spite of what the notation may suggest, \(\sqsubseteq\) will not necessarily be irreflexive. That is, we may have \(w \sqsubseteq w\) for some elements \(w \in W\). The reader needs to guard against this possibly misleading aspect of the symbols \(\sqsubseteq, \sqsupseteq\) throughout. The symbol \(<\) suggests irreflexivity even more strongly than \(\sqsubseteq\), so we avoid it.

Given an assignment \(h : PV \to \varphi(W)\), the tuple \(M = (W, \sqsubseteq, R, h)\) is called a Kripke model (for \(L\)). For \(w \in W\), we define \(M, w \models \varphi\) by induction on formulas \(\varphi\):

1. \(M, w \models \top\),
2. \(M, w \models p\) iff \(w \in h(p)\), for \(p \in PV\),
3. \(M, w \models \neg \varphi\) iff \(M, w \not\models \varphi\),
4. \(M, w \models \varphi \land \psi\) iff \(M, w \models \varphi\) and \(M, w \models \psi\),
5. \(M, w \models G \varphi\) iff \(M, u \models \varphi\) for all \(u \in W\) with \(w \sqsubseteq u\),
6. \(M, w \models H \varphi\) iff \(M, u \models \varphi\) for all \(u \in W\) with \(u \sqsubseteq w\),
7. \(M, w \models \Box \varphi\) iff \(M, u \models \varphi\) for all \(u \in W\) with \(Rwu\).

Let \(F = (W, \sqsubseteq, R)\) be a Kripke frame, and \(M = (W, \sqsubseteq, R, h)\) a Kripke model. We say that a formula \(\varphi\) is satisfiable (or satisfied) in \(M\), and that \(M\) satisfies \(\varphi\), if there is \(w \in W\) with \(M, w \models \varphi\), and satisfiable in \(F\) if there are \(h : PV \to \varphi(W)\) and \(w \in W\) with \((W, \sqsubseteq, R, h), w \models \varphi\). A formula \(\varphi\) is said to be valid in \(F\) (respectively, \(M\)) if \(\neg \varphi\) is not satisfiable in \(F\) (respectively, \(M\)).
2.4 General definitions

For a map $f : X \to Y$, and $X' \subseteq X$, we write $f(X')$ for \{f(x) : x \in X'\}. We write $\text{dom } f$ for $X$ and $\text{rng } f$ for $f(X)$.

**DEFINITION 2.1.** Let $W$ be a set, and $R$ a binary relation on it.

1. For $w, u \in W$, we write any of $Rwu, wRu, R(w, u)$ to indicate that $(w, u) \in R$.
2. We let $R^*$ denote the binary relation on $W$ defined by $R^*wu$ iff $Rwu \land \neg Ruw$.
3. For $w \in W$ we write $R(w) = \{u \in W : Rwu\}$.
4. A subset $X \subseteq W$ is said to be $R$-generated if $R(x) \subseteq X$ for every $x \in X$.
5. For $X \subseteq W$, we write $R \upharpoonright X$ for the binary relation $R \cap (X \times X)$ on $X$.
6. We say that $R$ is prelinear if for all $x, y \in W$ we have $Rx \lor x = y \lor Ryx$. (Note that more than one disjunct may hold. The term connex is also used in the literature, but here $R$ will usually be transitive, in which case ‘prelinear’ seems more evocative.)

**DEFINITION 2.2.** Let $\mathcal{M} = (W, \sqsubseteq, R, h)$ be a Kripke model.

1. Let $u, w \in W$. We write $w \sqsubseteq u$ to abbreviate $w \sqsubseteq u \lor w = u$, and $w \nor \sqsubseteq u$ to abbreviate $w \sqsubseteq u \land u \sqsubset w$. We take $u \nor \sqsubseteq w$ as synonymous for $w \sqsubseteq u$, and similarly for $\sqsupset$.
2. An element $w \in W$ is said to be $\sqsubseteq$-reflexive if $w \sqsubseteq w$, and $\sqsubseteq$-irreflexive, otherwise.
3. A $\sqsubseteq$-cluster of/in $\mathcal{M}$ is a $\sqsubseteq$-maximal non-empty subset $C \subseteq W$ such that $w \sqsubseteq u$ for all $w, u \in C$. This usage of ‘cluster’ is slightly different from that in (e.g.) [28]. Plainly, every member of a cluster is $\sqsubseteq$-reflexive.
4. Let $\mathcal{N} = (W', \sqsubseteq', R', h')$ be a Kripke model. We say that $\mathcal{N}$ is a submodel of $\mathcal{M}$, and write $\mathcal{N} \subseteq \mathcal{M}$, if $W' \subseteq W$, $\sqsubseteq' = \sqsubseteq | W'$, $R' = R \upharpoonright W'$, and $h'(p) = W' \cap h(p)$ for every atom $p \in PV$.
5. Let $\mathcal{N} \subseteq \mathcal{M}$ be as above. We say that $\mathcal{N}$ is an $R$-generated submodel (of $\mathcal{M}$) if $W'$ is an $R$-generated subset of $W$, a $\sqsubseteq$-generated submodel if $W'$ is a $\sqsubseteq$-generated subset of $W$, and a $\sqsupset$-generated submodel if $W'$ is a $\sqsupset$-generated subset of $W$.
6. We say that $\mathcal{N}$ is a generated submodel of $\mathcal{M}$ if it is an $R$-generated, a $\sqsubseteq$-generated, and a $\sqsupset$-generated submodel of $\mathcal{M}$.

**LEMMA 2.3.** Let $\mathcal{M}, \mathcal{N}$ be Kripke models as above, and suppose that $\mathcal{N}$ is a generated submodel of $\mathcal{M}$.

1. If $\sqsubseteq$ is transitive, then any $\sqsubseteq$-reflexive point $w \in W$ lies in a unique $\sqsubseteq$-cluster, namely, $\{u \in W : w \sqsupset u\}$.
2. $\mathcal{N}, w \models \varphi$ iff $\mathcal{M}, w \models \varphi$ for every $\mathcal{L}$-formula $\varphi$ and every $w \in W'$.
3. Every $\mathcal{L}$-formula that is valid in the frame $(W, \sqsubseteq, R)$ of $\mathcal{M}$ is valid in the frame $(W', \sqsubseteq', R')$ of $\mathcal{N}$.

**Proof.** We leave the proof of part 1 as an exercise. Part 2 is well known and easily proved by induction on $\varphi$. Part 3 follows from part 2. □
2.5 Linear orders

A linear order is a structure \((I, <)\), where \(I\) is a non-empty set and < is an irreflexive transitive binary relation on \(I\) that is prelinear according to definition 2.1(6): \( (I, <) \models \forall xy(x < y \lor x = y \lor x > y) \). Since < is irreflexive and transitive, exactly one disjunct holds, and we say in this case that < is linear. See, e.g., [27] for information about linear orders. We often write \((I, <)\) simply as \(I\). As usual, we let \(x \leq y\) abbreviate \(x < y \lor x = y\). A subset \(U \subseteq I\) is unbounded (in \(I\)) if for all \(x \in I\) there are \(y, z \in U\) with \(y < x < z\). An interval of \(I\) is a non-empty convex subset of \(I\). We will often regard an interval as a linear order in its own right, under the ordering induced from \(I\). We use standard notation for intervals specifiable by endpoints: if \(x, y \in I\) and \(x \leq y\) then \((x, y) = \{z \in I : x < z < y\}\), \([x, y) = \{z \in I : x \leq z < y\}\), \((−\infty, x) = \{z \in I : z < x\}\), etc. An open interval is one containing no least or greatest element.

3 Axioms

We now present a Hilbert system that, as we will show, axiomatises the \(L\)-logic of \(\mathbb{R}\). It is based on a system of Shehtman [28, §2] that was shown to axiomatise the \(L\)-logic of \(\mathbb{Q}\). The only difference is that we have added a ‘connectedness’ axiom, axiom 5.

3.1 The system

The axioms are as follows. We assume familiarity with Sahlqvist formulas in temporal logic: see, e.g., [3]. The axioms 2–4 are Sahlqvist formulas and their first-order correspondents are reproduced below. (The normality axioms can be turned into Sahlqvist formulas by replacing \(q\) by \(\neg q\); their correspondents are equivalent to \(\top\), and are omitted.) Each correspondent is true in a Kripke frame iff the axiom is valid in the frame. Moreover, the correspondents are true in the frame of the canonical model of the logic axiomatised by the system.

1. all propositional tautologies
2. axioms for dense linear time without endpoints:
   \[ G(p \rightarrow q) \rightarrow (Gp \rightarrow Gq) \]  
   normality
   \[ Gp \rightarrow GGp \]  
   transitivity: \(\forall xyz(x \subseteq y \land y \subseteq z \rightarrow x \subseteq z)\)
   \[ p \rightarrow GPp \]  
   \[ GGp \rightarrow Gp \]  
   \[ FPp \rightarrow p \lor Fp \lor Pp \]  
   density: \(\forall xy(x \subseteq y \rightarrow \exists z(x \subseteq z \land z \subseteq y))\)
3. S4 axioms for \(\Box\):
   \[ \Box(p \rightarrow q) \rightarrow (\Box p \rightarrow \Box q) \]  
   normality
   \[ \Box p \rightarrow p \]  
   \[ \Box p \rightarrow \Box \Box p \]  
   \[ \Box(p \rightarrow q) \rightarrow (\Box p \rightarrow \Box q) \]  
   transitivity: \(\forall xyz(R(x, y) \land R(y, z) \rightarrow R(x, z))\)
4. Shehtman’s ‘special axioms’:
(a) \(Hp \land p \land Gp \rightarrow \Box p\)
(b) \(Gp \rightarrow G\Box p\)
(c) \(Gp \land \Box p \rightarrow \Box Gp\)
(d) \(\Box p \rightarrow Fp\)

5. \(F(p \land Fq) \land F(\neg p \land Fq) \rightarrow F(\Diamond p \land \Diamond \neg p \land Fq)\) (connectedness)

6. all mirror images of the above axioms (swap \(G\) with \(H\), and \(F\) with \(P\); also swap \(\Box\) with \(\sqcap\) in the correspondents).

The rules of inference are the standard ones:

1. modus ponens: \(\varphi, \varphi \to \psi \quad \psi\)
2. generalisation: \(\varphi \quad G\varphi, \quad H\varphi, \quad \Box \varphi\)
3. substitution: \(\varphi(p) \quad \varphi(\psi/p)\)

Some mirror images, such as \(Hp \rightarrow HHp\), are redundant and can be omitted. We have not investigated the exact extent to which this can be done.

As usual, the logic axiomatised by this system is the smallest set \(L\) of \(L\)-formulas that contains all the axioms listed above and is closed under the rules of inference. We say that an \(L\)-formula \(\varphi\) is provable in the system if \(\varphi \in L\), and consistent if \(\neg \varphi \notin L\). A set \(\Gamma\) of \(L\)-formulas is consistent if \(\gamma_0 \land \ldots \land \gamma_n\) is consistent for every \(n \in \mathbb{N}\) and \(\gamma_0, \ldots, \gamma_n \in \Gamma\), and maximal consistent if it is consistent but has no proper consistent extension.

We aim to show that \(L\) is the \(L\)-logic of \(\mathbb{R}\). The inclusion ‘\(\subseteq\)’ (soundness) is straightforward:

**THEOREM 3.1.** The system is sound over \(\mathbb{R}\).

**Proof (sketch).** All axioms other than axiom 5 are shown to be valid over any dense flow of time without endpoints in [28, lemma 2.2(2)]. Axiom 5 is valid over \(\mathbb{R}\) because every interval of \(\mathbb{R}\) is connected. Indeed, assume that for some model \((\mathbb{R}, h)\) and \(t \in \mathbb{R}\) we have

\[(\mathbb{R}, h), t \models F(p \land Fq) \land F(\neg p \land Fq).\]

Let \(v_1, v_2 > t\) satisfy \((\mathbb{R}, h), v_1 \models p \land Fq\) and \((\mathbb{R}, h), v_2 \models \neg p \land Fq\). We can find \(u > \max(v_1, v_2)\) with \(u \in h(q)\). Assume wlog. that \(v_1 < v_2\).

\[s = \sup\{x \in \mathbb{R} : \forall y(v_1 \leq y < x \rightarrow y \in h(p))\}\]

Then \(t < v_1 \leq s \leq v_2 < u\). Hence, \((\mathbb{R}, h), s \models Fq\). By definition of \(s\), we have \((\mathbb{R}, h), s \models \Diamond p \land \Diamond \neg p\). We deduce that \((\mathbb{R}, h), t \models F(\Diamond p \land \Diamond \neg p \land Fq)\) as required.

The inference rules obviously preserve validity.

\(\square\)
3.2 Simple theorems of the system

The first three lemmas do not use the connectedness axiom 5 or its mirror image.

**Lemma 3.2.** \( F\top \) and \( P\top \) are provable in the system.

*Proof.* As \( \top \) is a tautology, it is provable, and we get \( \Box \top \) by \( \Box \)-generalisation. By axiom 4d, we prove \( F\top \). We prove \( P\top \) similarly. \( \square \)

**Lemma 3.3.** \( G\neg p \land HFp \rightarrow \Diamond p \) is provable in the system.

*Proof.* We can prove \( G\neg p \land \Box \neg p \rightarrow \Box G\neg p \) by axiom 4c. By the mirror image of axiom 4d we have \( \Box G\neg p \rightarrow PG\neg p \). Using propositional tautologies we deduce \( G\neg p \land \Box \neg p \rightarrow \neg HFp \), and then the result. \( \square \)

The connectedness axiom (5) has an important consequence: the well known Prior axiom
\[
Fq \land FG\neg q \rightarrow F(G\neg q \land HFq).
\]
(3.1)

We will prove this using the following lemma.

**Lemma 3.4.** \( \Diamond Gq \rightarrow Gq \) and \( \Diamond Hq \rightarrow Hq \) are provable in the system.

*Proof.* The following are provable:

1. \( \Diamond Gq \rightarrow GP\Diamond Gq \) by axiom \( p \rightarrow GPp \)
2. \( P\Diamond Gq \rightarrow PGq \) \( Gq \)-instance of contrapositive of axiom 4b (\( Hp \rightarrow H\Box p \))
3. \( GP\Diamond Gq \rightarrow GP\Diamond Gq \) from previous by \( G \)-generalisation and normality
4. \( PGq \rightarrow q \) contrapositive of temporal axiom \( p \rightarrow HFp \)
5. \( GP\Diamond Gq \rightarrow Gq \) from previous by \( G \)-generalisation and normality

The result now follows from lines 1, 3, and 5 by propositional tautologies. The proof of \( \Diamond Hq \rightarrow Hq \) is a mirror image. \( \square \)

Now we will use the connectedness axiom for the first time.

**Corollary 3.5.** The Prior axiom \( Fq \land FG\neg q \rightarrow F(G\neg q \land HFq) \) and its mirror image are provable in the system.

*Proof.* We give a more informal proof along the lines of the preceding lemma. Assume \( Fq \land FG\neg q \). Using the density axiom, this yields \( FFq \land FG\neg q \). Taking \( p = G\neg q \) and \( q = \top \) in the connectedness axiom (axiom 5) gives \( F(G\neg q \land F\top) \land F(\neg G\neg q \land F\top) \rightarrow F(\Diamond G\neg q \land \Diamond \neg G\neg q \land F\top) \). By lemma 3.2, \( F\top \) is equivalent to \( \top \), so this reduces to

\[
FG\neg q \land FFq \rightarrow F(\Diamond G\neg q \land \Diamond Fq).
\]

So we obtain \( F(\Diamond G\neg q \land \Diamond Fq) \). Now by standard temporal logic, we can prove \( Fq \rightarrow HF(Fq) \) and \( HF(Fq) \rightarrow HFq \). This gives us \( F(\Diamond G\neg q \land \Diamond HFq) \). By lemma 3.4, we obtain \( F(G\neg q \land HFq) \) as required. The mirror image can be derived similarly. \( \square \)

**Remark 3.6.** In connection with the consequent of the Prior axiom, we point out that if \( M \) is a Kripke model, \( w \in M, \varphi \) an \( \mathcal{L} \)-formula, and \( M, w \models G\neg \varphi \land HF\varphi \), then \( w \) is \( \Box \)-irreflexive. For if \( w \sqsubset w \) then as \( M, w \models HF\varphi \) we have \( M, w \models F\varphi \), contradicting \( M, w \models G\neg \varphi \).
4 Some facts about the $L$-logic of $\mathbb{R}$

Here we prove some fairly straightforward results about the $L$-logic of $\mathbb{R}$.

4.1 Complexity

We will see below that the $L$-logic of $\mathbb{R}$ does not have the finite model property. Since this property is often used to show decidability, it may be surprising that the logic is decidable [28, p. 256]. We begin by establishing its complexity.

**THEOREM 4.1.** The problem of deciding whether an $L$-formula is valid over $\mathbb{R}$ is PSPACE-complete.

**Proof (sketch).** We assume knowledge of temporal logic with Until and Since ($U, S$) as in [26], where it is proved that the problem of determining satisfiability over $\mathbb{R}$ of a formula written with $U, S$ is PSPACE-complete. Given an $L$-formula $\varphi$, introduce a new propositional atom $q_\psi$ for each subformula $\psi$ of $\varphi$, and define the formula $\hat{\psi}$ as follows, where $\forall \psi$ abbreviates $\psi \land \neg U(\neg \psi, T) \land \neg S(\neg \psi, T)$:

- $\hat{T} = \forall q_T$
- $\hat{p} = \forall (p \leftrightarrow q_p)$ for $p \in PV$
- $\hat{\neg \psi} = \forall (q_{\neg \psi} \leftrightarrow \neg q_\psi)$
- $\hat{\psi \land \chi} = \forall (q_{\psi \land \chi} \leftrightarrow q_\psi \land q_\chi)$
- $\hat{F \psi} = \forall (q_{F \psi} \leftrightarrow U(q_\psi, T))$
- $\hat{P \psi} = \forall (q_{P \psi} \leftrightarrow S(q_\psi, T))$
- $\hat{\Box \psi} = \forall (q_{\Box \psi} \leftrightarrow q_\psi \land U(T, q_\psi) \land S(T, q_\psi))$.

Let $\varphi^*$ be the conjunction of all $\hat{\psi}$ for subformulas $\psi$ of $\varphi$, together with $q_\varphi$. It can be checked that $\varphi$ is satisfiable over $\mathbb{R}$ iff $\varphi^*$ is, and that $\varphi^*$ can be constructed from $\varphi$ in polynomial time. Given $\varphi$, we may construct $\varphi^*$ and then decide its satisfiability over $\mathbb{R}$ in PSPACE [26]. The combined procedure can be done in polynomial space, so the satisfiability, and hence the validity, of $\varphi$ can be decided in PSPACE. The logic of $\mathbb{R}$ with $\Box$ alone is S4 [20], which is already PSPACE-hard [16].

4.2 Strong completeness

A Hilbert system (of axioms and rules) is said to be *sound* if all satisfiable formulas are consistent, and *strongly complete* if any consistent set of formulas using in all only countably many atoms is satisfiable.

**THEOREM 4.2.** There is no sound and strongly complete Hilbert system for the $L$-logic of $\mathbb{R}$.
Proof. Let $\Sigma$ be the following set of formulas written with atoms $p, q, r$:

\[
\begin{align*}
\Box p \\
F(r \land \neg r) \\
G(r \lor Fr \rightarrow \Box p \lor \Box q) \\
F(\neg p \land F(\neg q \land F(\cdots \land Fr)\cdots)) \quad \text{for each integer } n \geq 1
\end{align*}
\]

$n$ brackets

It is easy to see that any finite subset of $\Sigma$ is satisfiable over $\mathbb{R}$. However, $\Sigma$ itself is not satisfiable over $\mathbb{R}$. For suppose that $\Sigma$ is satisfied at 0 and $r \land \neg r$ is true at 1, say. By the first and third formulas, each $x \in [0, 1]$ belongs to some open interval $I_x \subseteq \mathbb{R}$ with $I_x \subseteq h(p)$ or $I_x \subseteq h(q)$. By the Heine–Borel theorem, $[0, 1]$ is compact, so there are $n \in \mathbb{N}$ and $x_0 < \cdots < x_n$ in $[0, 1]$ such that $[0, 1] \subseteq \bigcup_{i \leq n} I_{x_i}$. By the final set of formulas, there are $0 < y_0 < y_1 < \cdots < y_n < 1$ with $y_j \notin h(p)$ if $j$ is even and $y_j \notin h(q)$ if $j$ is odd (each $j \leq n$). Now by the pigeonhole principle and convexity of the $I_{x_i}$, there are $i, j < n$ with $y_j, y_{j+1} \in I_{x_i}$. But $I_{x_i} \subseteq h(p)$ or $I_{x_i} \subseteq h(q)$, a contradiction.

If the $\mathcal{L}$-logic of $\mathbb{R}$ had a sound and strongly complete Hilbert system, then since $\Sigma$ is finitely satisfiable, it would be consistent and so satisfiable, contradicting the above. $\square$

### 4.3 Kripke completeness

Finally, we consider Kripke completeness. I would like to thank Nick Bezhanishvili for helpful discussions on this material. First, a minor lemma, used only here.

**Lemma 4.3.** Let $\mathcal{F} = (W, \sqsubset, R)$ be a Kripke frame that validates the axioms of §3.1. Suppose that $w, u, x \in W$ satisfy $w \sqsubset u$, $w \sqsubset x$, and $\neg (x \sqsubset u)$. Then there is $y \in W$ satisfying $w \sqsubset y$, $\neg (y \sqsubset u)$, and $\text{Ryu}$.

**Proof.** Let $w, u, x \in W$ be as stated. Let $h : PV \rightarrow W$ be an assignment with $h(p) = \{u\}$, and let $\mathcal{N} = (W, \sqsubset, R, h)$. Since $\neg (x \sqsubset u)$, we have $\mathcal{N}, x \models G \neg p$. As $w \sqsubset u, x$, this gives $\mathcal{N}, w \models Fp \land HFp$. As all axioms are valid in $\mathcal{F}$ and frame validity is preserved by the inference rules, by corollary 3.5 the Prior axiom (3.1) is valid in $\mathcal{F}$, so $\mathcal{N}, w \models (G \neg p \land HFp)$. Hence there is $y \in W$ with $w \sqsubset y$ and

$$\mathcal{N}, y \models G \neg p \land HFp. \tag{4.1}$$

Hence, $\neg (y \sqsubset u)$. By (4.1) and lemma 3.3, $\mathcal{N}, y \models \Diamond p$. So $\text{Ryu}$. $\square$

We will now consider the following formula $\theta$, where $a, b$ are atoms:

$$\theta = H \neg a \land H \neg b \land \neg a \land \neg b \land \Diamond a \land \Diamond b \land G \neg (\Diamond a \land \Diamond b) \land FG \neg a. \tag{4.2}$$

**Lemma 4.4.** The formula $\theta$ is satisfiable over $\mathbb{R}$, but is not satisfiable in any Kripke model whose frame validates the axioms of §3.1.
Proof. Let $h : PV \rightarrow \wp(\mathbb{R})$ be an assignment satisfying $h(a) = \{1/2^n : n \in \mathbb{N}\}$ and $h(b) = \{2/3^n : n \in \mathbb{N}\}$. Evidently, $(\mathbb{R}, h), 0 \models \theta$. So $\theta$ is satisfiable over $\mathbb{R}$.

Let $\mathcal{M} = (W, \sqsubseteq, R, h)$ be a Kripke model whose frame $\mathcal{F} = (W, \sqsubseteq, R)$ validates the axioms of $\S 3.1$. Let $w \in W$ and assume for contradiction that $\mathcal{M}, w \models \theta$.

Recall from definition 2.1 that $R(w) = \{u \in W : Rwu\}$. Plainly, $\mathcal{M}, w \models \Diamond a \land b$, so there are $u, v \in R(w)$ with $\mathcal{M}, u \models a$ and $\mathcal{M}, v \models b$. Now the correspondents of the axioms in $\S 3.1$, where given, are all true in $\mathcal{F}$. By (the correspondent of) axiom 4a, $u \sqsubseteq w \lor u \sqsubseteq w$. As $\mathcal{M}, w \models H\neg a \land \neg a$, we cannot have $u \sqsubseteq w$. So $u \sqsupset w$. Since also $Rwv$, by axiom 4b we obtain $u \sqsupset v$. Similarly, $v \sqsubseteq u$. By the S4 axioms, $\sqsubseteq$ is transitive, so $\{u, v\}$ is contained in a $\square$-cluster.

As $\mathcal{M}, w \models FG\neg a$, we can choose $x \in W$ with $w \sqsubseteq x$ and $\mathcal{M}, x \models G\neg a$. Since $\mathcal{M}, u \models a$, we have $\neg(x \sqsubseteq u)$. So by lemma 4.3, there is $y \in W$ with $w \sqsubseteq y$, $\neg(y \sqsubseteq u)$, and $Ryu$. But also, $u \sqsubseteq v$, so by axiom 4c we obtain $Ryv \lor y \sqsubseteq v$.

If $Ryv$, then both $u, v \in R(y)$, so $\mathcal{M}, y \models \Diamond a \land \Diamond b$. Since $w \sqsubseteq y$, we obtain $\mathcal{M}, w \models F(\Diamond a \land \Diamond b)$, contradicting that $\mathcal{M}, w \models \theta$. If instead $y \sqsubseteq v$, then since $v \sqsubseteq u$ we have $y \sqsubseteq u$, contradicting that $\neg(y \sqsubseteq u)$. Either way, our assumption that $\mathcal{M}, w \models \theta$ has led to a contradiction. \hfill $\square$

Readers wondering whether $\theta$ could be simplified to a formula with only one atom should bear in mind that $H\neg a \land \neg a \land \Diamond a \land G\neg a$ is not satisfiable over $\mathbb{R}$, and its negation is provable (the proof uses axiom 4a and the S4 reflexivity axiom for $\Box$). Separately, lemma 4.4 fails if the final conjunct $FG\neg a$ is omitted from $\theta$. We will return to this example in $\S 5$ and $\S 7.6$.

Recall that a modal logic $L$ is said to be Kripke complete (respectively, to have the finite model property) if there exists a class $\mathcal{K}$ of (resp. finite) Kripke frames such that $L$ is the set of all modal formulas that are valid in every frame in $\mathcal{K}$.

**THEOREM 4.5.** The $L$-logic of $\mathbb{R}$ is not Kripke complete and does not have the finite model property.

Proof. If the $L$-logic of $\mathbb{R}$ were the logic of a class $\mathcal{K}$ of Kripke frames of the form $(W, \sqsubseteq, R)$, then as the formula $\theta$ in (4.2) is satisfiable over $\mathbb{R}$, it would be satisfiable over a frame in $\mathcal{K}$. By lemma 4.4, such a frame could not validate the axioms of $\S 3.1$. So by theorem 3.1, it could not validate the logic of $\mathbb{R}$ either. \hfill $\square$

As N. Bezhanishvili has observed, the $L$-logic of $\mathbb{R}$ is a ‘naturally occurring’ example of a non-Kripke complete logic.

5 Towards completeness

The main aim of the paper is to show that the Hilbert system given in $\S 3.1$ is sound and complete for the $L$-logic of $\mathbb{R}$. In this section, we take some first steps in that direction.
5.1 A problem

We begin by observing that certain naïve approaches will not succeed. For example, we might try to prove that every consistent formula is satisfiable in some finite Kripke model whose frame \((W, \sqsupset, R)\) has the following special form. Ordered by \(\sqsupset\), which is transitive and prelinear, it falls into a sequence

\[ C_0 \sqsupset u_0 \sqsupset C_1 \sqsupset u_1 \sqsupset \cdots \sqsupset u_{n-1} \sqsupset C_n, \]

where \(n \geq 0\), the \(C_i\) are \(\sqsupset\)-clusters, the \(u_i\) are \(\sqsupset\)-irreflexive, the relation \(\sqsupset\) is defined between sets and points as in definition 5.1(1), and \(R(u_i) = C_i \cup \{u_i\} \cup C_{i+1}\) for each \(i < n\). (Recall that \(R(u_i) = \{w \in W : Ru_i w\}\).) We could also require that every cluster is connected as an \(R\)-frame — see definition 5.2 for the meaning of this. It would then be not so hard to construct a model over \(R\) satisfying the formula.

This idea is unlikely to work — by theorem 4.5, the logic of \(R\) is not characterised by any class of finite frames at all. And in fact, the formula \(\theta\) of (4.2) — which is consistent since it is satisfiable over \(R\) — is not satisfiable in any Kripke model of this form. For, \(\theta\) being true at a world \(w\) would force \(w\) to be irreflexive — say \(w = u_i\) — and \(a\) and \(b\) to be true at some worlds in the cluster \(C_{i+1}\) immediately following \(u_i\) in the order \(\sqsupset\). This cluster could not be \(\sqsupset\)-final in the model because of the conjunct \(FG\neg a\) of \(\theta\). So \(i + 1 < n\). But now, \(\lozenge a \land \lozenge b\) would be true at \(u_{i+1}\), contradicting the truth of \(G\neg (\lozenge a \land \lozenge b)\) at \(u_i\).

5.2 \(\Psi\)-linked models

So it seems that we are forced to work with Kripke models that may contain adjacent \(\sqsupset\)-clusters with no intervening irreflexive point. (Since the \(\mathcal{L}\)-logic of \(R\) is not Kripke complete, it seems that we cannot work with frames and have to use models.) We will focus our attention on ‘nice’ models in which any two such clusters contain ‘similar’ points. We will show that any consistent formula is satisfiable in a nice Kripke model, and that any such model can be transformed into a model over \(R\). To define ‘nice’, we need the following somewhat disparate preliminary definitions.

**Definition 5.1.** Let \(\mathcal{M} = (W, \sqsupset, R, h)\) be a Kripke model.

1. For \(X, Y \subseteq W\), we write \(X \sqsupset Y\) if \(x \sqsupset y\) for every \(x \in X\) and \(y \in Y\). We abbreviate \(\{x\} \sqsupset Y\) to \(x \sqsupset Y\), etc.

2. We say that an ordered pair \((C, D)\) of \(\sqsupset\)-clusters in \(\mathcal{M}\) is
   - *consecutive* (in \(\mathcal{M}\)) if \(C \neq D\) and \(\{u \in W : u \sqsupset\text{-reflexive, } C \sqsupset u \sqsupset D\} = C \cup D\),
   - *adjacent* (in \(\mathcal{M}\)) if \(C \neq D\) and \(\{u \in W : C \sqsupset u \sqsupset D\} = C \cup D\).

In each case, \(C \sqsupset D\). Consecutive clusters have no \(\sqsupset\)-reflexive points between them, but may have \(\sqsupset\)-irreflexive ones. Adjacent clusters have nothing between them.

**Definition 5.2.** A frame \((W, R)\) is said to be *connected* if there do not exist non-empty disjoint \(R\)-generated subsets \(X, Y \subseteq W\) with \(W = X \cup Y\).
**DEFINITION 5.3.** Let Ψ be a set of $\mathcal{L}$-formulas.

1. We write $B\Psi$ for the set of formulas in Ψ of the form $\Box \theta$, $G\theta$, or $H\theta$ (the ‘box-formulas’).

2. Let $\mathcal{M} = (W, \sqsubseteq, R, h)$ be a Kripke model. We define an equivalence relation $\equiv^\mathcal{M}_\Psi$ on $W$ by: $c \equiv^\mathcal{M}_\Psi d$ iff for every $\psi \in \Psi$, we have $\mathcal{M}, c \models \psi$ iff $\mathcal{M}, d \models \psi$.

We can now give our definition of ‘nice’ model:

**DEFINITION 5.4.** Let Ψ be a set of $\mathcal{L}$-formulas. We say that a Kripke model $\mathcal{M} = (W, \sqsubseteq, R, h)$ is $\Psi$-linked if:

1. $W$ is finite.

2. The frame $(W, \sqsubseteq, R)$ validates all axioms of §3.1 (including mirror images), except possibly the connectedness axiom 5 and its mirror image.

3. The relation $\sqsubseteq$ is prelinear (see definition 2.1(6)).

4. For every $\sqsubseteq$-cluster $C \subseteq W$, the frame $(C, R \downarrow C)$ is connected.

5. For every pair $(C, D)$ of adjacent $\sqcup$-clusters in $\mathcal{M}$, there are $c \in C$ and $d \in D$ with $c \equiv^\mathcal{M}_{B\Psi} d$.

In a $\Psi$-linked model $\mathcal{M}$, adjacent clusters are ‘linked’ by ‘similar’ (formally, $\equiv^\mathcal{M}_{B\Psi}$-equivalent) points. Agreement of these points on formulas $\Box \theta$ in Ψ is critical for our later work — in lemma 7.25 in particular. Their agreement on formulas $G\theta$ and $H\theta$ is more a convenience that allows a simple definition of ‘nice’ model. Condition 4 is weaker than saying that the frame of $\mathcal{M}$ validates the connectedness axiom 5. For example, if $\mathcal{M}$ consists of two $\sqsubseteq$-reflexive points $c, d$, with $c \sqsubseteq d$, $\neg Rcd$, $\neg Rdc$, $\mathcal{M}, c \models p$, and $\mathcal{M}, d \models \neg p$, then $\mathcal{M}$ is $\emptyset$-linked but does not validate the connectedness axiom.

### 5.3 Structure of $\Psi$-linked models

By definition 5.4, the frame of a $\Psi$-linked model validates the Shehtman axioms, and these impose considerable structure on Kripke frames validating them. The following lemma sheds a lot of light on this structure. It can be obtained from [28, lemmas 3.5–3.6], but we give a proof to make the paper more self-contained.

**LEMMA 5.5 (λ, ρ-lemma).** Let $\mathcal{F} = (W, \sqsubseteq, R)$ be a Kripke frame that validates the axioms of §3.1 except possibly the connectedness axiom 5 and its mirror image, and let $w \in W$.

1. Every $\sqcup$-cluster in $\mathcal{F}$ is an $R$-generated subset of $W$.

2. If $w$ is $\sqsubseteq$-reflexive then $R(w)$ is a subset of a $\sqsubseteq$-cluster.

3. If $w$ is $\sqsubseteq$-irreflexive, then there are disjoint $\sqsubseteq$-clusters $\lambda(w), \rho(w)$ such that $R(w) = \lambda(w) \cup \{w\} \cup \rho(w)$. For every $t \in W$ we have $t \sqsubseteq w$ iff $t \sqsubseteq \lambda(w)$, and $w \sqsubseteq t$ iff $\rho(w) \sqsubseteq t$.
Proof. Since $\mathcal{F}$ validates all axioms in §3.1 with first-order correspondents, those correspondents are true in $\mathcal{F}$. To prove part 1 of the lemma, let $C \subseteq W$ be a $\sqsubseteq$-cluster and let $w \in C$. By lemma 2.3, $C = \{ u \in W : u \sqsubseteq w \}$ (recall from definition 2.2 that $u \sqsubseteq w$ denotes that $u \sqsubseteq w \land w \sqsubseteq u$). By axiom 4b and its mirror image, $C$ is $R$-generated.

For part 2, suppose that $w \sqsubset w$. By lemma 2.3, $w$ is contained in a $\sqsubseteq$-cluster $C = \{ u \in W : u \sqsubseteq w \}$. By part 1, $C$ is $R$-generated, so $R(w) \subseteq C$.

For part 3, suppose that $-(w \sqsubset w)$ and let
\[
\lambda(w) = R(w) \cap \{ u \in W : u \sqsubset w \},
\]
\[
\rho(w) = R(w) \cap \{ u \in W : w \sqsubset u \}.
\]
These sets are non-empty by axiom 4d and its mirror image, and disjoint as $w$ is irreflexive and $\sqsubset$ transitive. By axiom 4a we have $R(w) = \lambda(w) \cup \{ w \} \cup \rho(w)$.

We show that $\lambda(w)$ is a $\sqsubseteq$-cluster. If $t \in W$ and $u \in \lambda(w)$, then axiom 4b and $\sqsubseteq$-transitivity yield
\[
t \sqsubseteq w \text{ iff } t \sqsubseteq u. \tag{5.1}
\]
Recalling that $\lambda(w) \neq \emptyset$, pick arbitrary $u \in \lambda(w)$. Taking $t = u$ in (5.1), we see that $u$ is $\sqsubseteq$-reflexive, so by lemma 2.3 again, the set $U = \{ v \in W : v \sqsubseteq w \}$ is a $\sqsubseteq$-cluster.

We show that $\lambda(w) = U$. By (5.1), $t \sqsubseteq v$ for all $t, v \in \lambda(w)$, and it follows that $\lambda(w) \subseteq U$. To show that $U \subseteq \lambda(w)$, let $t \in U$ be arbitrary. Since $u \sqsubseteq w$, by $\sqsubseteq$-transitivity we have $t \sqsubseteq w$. Also, $Ruv \land u \sqsubseteq t$, so by axiom 4c, $w \sqsubseteq t \lor Rwt$.

If $w \sqsubseteq t$, then as $t \sqsubset w$ and $\sqsubseteq$ is transitive, we would have $w \sqsubset w$, contradicting irreflexivity of $w$. So $-(w \sqsubset t)$, and hence $Rwt$. We already have $t \sqsubset w$, so $t \in \lambda(w)$. As $t \in U$ was arbitrary, $U \subseteq \lambda(w)$ as required.

The last claim in the lemma (for $\lambda$) is immediate from (5.1). The case of $\rho$ is handled similarly. 

It follows from the lemma that for $\sqsubset$-irreflexive $w$ we have $u \sqsubseteq w \sqsubseteq v$ for every $u \in \lambda(w)$ and $v \in \rho(w)$, by taking $t = u$ and $t = v$. That is, $\lambda(w) \sqsubseteq w \sqsubseteq \rho(w)$. We can think of $\lambda(w)$ as the set of points lying infinitesimally near to $w$ in the past, and $\rho(w)$ as the set of points lying infinitesimally near to $w$ in the future.

We can now elucidate the structure of a $\Psi$-linked model $\mathcal{M} = (W, \sqsubseteq, R, h)$. Recall that $\xi \sqsubseteq \eta$ means $\xi \sqsubseteq \eta \land \eta \sqsubseteq \xi$. For $x, y \in W$ define $x \sim y$ iff $x \sqsubset y \lor x \sqsubseteq y$. As $\sqsubseteq$ is transitive, $\sim$ is an equivalence relation on $W$. Each equivalence class is either a singleton consisting of an $\sqsubseteq$-irreflexive point, or (by lemma 2.3) a $\sqsubseteq$-cluster. As $\sqsubseteq$ is prelinear, we can enumerate the clusters without repetitions as $C_0, \ldots, C_k$, with $C_0 \sqsubseteq C_1 \sqsubseteq \cdots \sqsubseteq C_k$. Each remaining $\sim$-class, if any, is a singleton $\{ u \}$ with $u \sqsubseteq$-irreflexive. The frame $\mathcal{F} = (W, \sqsubseteq, R)$ validates the axioms required by lemma 5.5, so for each such $u$ the sets $\lambda(u), \rho(u)$ are defined and are $\sqsubseteq$-clusters. Say, $\lambda(u) = C_i$. By the lemma, $C_i \sqsubseteq u$, and $u \sqsubseteq w$ iff $\rho(u) \sqsubset w$ for each $w \in W$. It follows that $i < k$ and $\rho(u) = C_{i+1}$. If $u, v$ are irreflexive and $u \sqsubset v$, then by the lemma, $u \sqsubset \rho(u) \sqsubset \lambda(v) \sqsubset v$ (possibly $\rho(u) = \lambda(v)$), so for each $i < k$ there is at most one irreflexive point lying between $C_i$ and $C_{i+1}$.

We conclude that for some finite $k \geq 0$, the frame $(W, \sqsubseteq)$ is the union of distinct $\sqsubseteq$-clusters $C_0 \sqsubseteq C_1 \sqsubseteq \cdots \sqsubseteq C_k$ and $\sqsubset$-irreflexive points $u_i$ ($i \in I$) for some $I \subseteq
\{0, \ldots, k - 1\}, with \( C_i = \lambda(u_i) \sqsubset u_i \sqsubset \rho(u_i) = C_{i+1} \) for each \( i \in I \). We never get two adjacent irreflexive points. This is as in the suggested form of frames in §5.1, except that we may get two adjacent \( \sqsubset \)-clusters with no intervening irreflexive point. In this case, they are linked by containing \( \equiv^M_{\Psi} \)-equivalent points.

### 5.4 Problem resolved

We saw in §5.1 that the formula \( \theta \) of (4.2) is not satisfiable in any model whose frame is as described there. Let us now show that \( \theta \) is satisfiable in a linked model.

**Proposition 5.6.** The formula

\[
\theta = H\neg a \land H\neg b \land \neg a \land \neg b \land \Diamond a \land \Diamond b \land G\neg (\Diamond a \land \Diamond b) \land FG\neg a
\]

of (4.2) is satisfied in a \( \Psi \)-linked model, where \( \Psi \) is the set of subformulas of \( \theta \).

**Proof.** The formula \( \theta \) is true at world \( u_0 \) in the Kripke model \( \mathcal{M} = (W, R, \sqsubset, h) \) shown in figure 1. In the figure, the black dots are \( \sqsubset \)-irreflexive and the white dots are \( \sqsubseteq \)-reflexive. The relation \( \sqsubset \) is given by the left-to-right ordering, except within each \( \sqsubset \)-cluster \( C_i \) (\( i \leq 3 \)) where of course all points are \( \sqsubseteq \)-related. The relation \( R \) is given by the reflexive closure of the arrows. The atoms \( a, b \) are true only where shown at \( u_2 \) and the two upper points in \( C_1 \).

Let \( \Psi \) be the set of subformulas of \( \theta \). Recalling that \( \Diamond \) abbreviates \( \neg \Box \neg \) and \( F \) abbreviates \( \neg G \neg \), the set \( B\Psi \) of ‘box-formulas’ in \( \Psi \) is

\[
B\Psi = \{ H\neg a, H\neg b, \Box \neg a, \Box \neg b, G \neg (\Diamond a \land \Diamond b), GF a, G \neg a \}.
\]

We claim that \( \mathcal{M} \) is \( \Psi \)-linked. It is finite, and its frame validates all axioms in §3.1 (including mirror images), except possibly the connectedness axiom 5 and its mirror image. Obviously, the relation \( \sqsubseteq \) is prelinear and the frame \( (C, R \upharpoonright C) \) is connected for each \( \sqsubseteq \)-cluster \( C \). The only adjacent \( \sqsubset \)-clusters in \( \mathcal{M} \) are \( C_1 \) and \( C_2 \), and the lower dots \( d_1, s_2 \) in them are \( \equiv^M_{\Psi} \)-equivalent — \( \Box \neg a, \Box \neg b \), and \( G \neg (\Diamond a \land \Diamond b) \) are true at both of them, and \( H\neg a, H\neg b, GF a \), and \( G \neg a \) are false. So \( \mathcal{M} \) is indeed \( \Psi \)-linked.

\[\square\]

We will return to this example in §7.6.
5.5 Strategy of completeness proof

Our approach to proving completeness will now be as follows.

Step 1. We show that any formula $\varphi_0$ that is consistent with the system of §3.1 is satisfiable in a $\Psi$-linked Kripke model, where $\Psi$ is the set of subformulas of $P\varphi_0$. This is done in §6.

Step 2. Given any $\Psi$-linked model, where $\Psi$ is a finite set of formulas closed under subformulas, we construct a model over $\mathbb{R}$ that satisfies the same formulas from $\Psi$. This is done in §7.

These two steps are of roughly equal length and can be read in either order. Readers may prefer to read §7 first, as $\Psi$-linked models may be better motivated that way. Completeness of the system follows immediately by putting the two steps together — this will be done in theorem 8.1.

6 Consistent formulas have linked models

In this section we prove the following.

**Theorem 6.1.** Let $\varphi_0$ be an $\mathcal{L}$-formula that is consistent with the system of §3.1. Let $\Psi$ be a finite set of $\mathcal{L}$-formulas containing $P\varphi_0$ and closed under taking subformulas. Then $\varphi_0$ is satisfiable in a $\Psi$-linked Kripke model.

To prove it, we will successively construct five Kripke models $M_0, \ldots, M_4$ satisfying $\varphi_0$ and getting closer to our goal. The first three are exactly as in Shehtman’s axiomatisation of the logic of $F, P, \square$ over $\mathbb{Q}$ in [28]. The last, $M_4$, will be a $\Psi$-linked model satisfying $\varphi_0$. Each $M_i$ will be written $(W_i, \sqsubseteq, R_i, h_i)$, but sometimes we drop the index $i$ from these entries. Also, we sometimes identify (notationally) $M_i$ with its domain $W_i$.

0. $M_0$ is the canonical model.

1. $M_1$ is a generated submodel of $M_0$ satisfying $\varphi_0$, in which the relation $\sqsubseteq$ is prelinear.

2. $M_2$ is got by filtrating all $\sqsubseteq$-clusters of $M_1$, which consequently become finite.

3. $M_3$ is a finite $R$-generated submodel of $M_2$ got by selective filtration for $\sqsubseteq$.

   We use prelinearity and the Prior axiom to obtain it.

4. $M_4$ is obtained from $M_3$ by adding some extra points to arrange that any two adjacent clusters contain $\equiv^M_{B\Psi}$-equivalent points. We use the Prior axiom and induction on the number of ‘$\equiv^M_{B\Psi}$-types’ of points in an interval.

As we go, we will indicate why we apparently cannot jump from our latest model directly to a model of $\varphi_0$ over $\mathbb{R}$.

Now to the details. Let $\varphi_0$ be an $\mathcal{L}$-formula consistent with the system defined in §3.1. We will explain in turn how each model $M_0, \ldots, M_4$ is constructed.
6.1 Model $\mathcal{M}_0$

This is just the canonical model of the system given in §3.1, over the set $PV$ of atoms. So $W_0$ is the set of all maximal consistent sets of $\mathcal{L}$-formulas. We write $\Gamma, \Delta, \Xi, \Theta, \ldots$ for arbitrary members of $W_0$. The relations and assignment are defined by:

- $\Gamma \sqsubseteq_0 \Delta$ iff $\varphi \in \Delta$ for every formula $G\varphi \in \Gamma$ (this is equivalent to each of the three statements $\varphi \in \Delta \Rightarrow F\varphi \in \Gamma$, $H\varphi \in \Delta \Rightarrow \varphi \in \Gamma$, and $\varphi \in \Gamma \Rightarrow P\varphi \in \Delta$),
- $\Gamma R_0 \Delta$ iff $\varphi \in \Delta$ for every formula $\Box \varphi \in \Gamma$ (equivalently, $\varphi \in \Delta \Rightarrow \Diamond \varphi \in \Gamma$),
- $h_0(p) = \{\Gamma \in W_0 : p \in \Gamma\}$ for each atom $p \in PV$.

We assume familiarity with basic facts about canonical models — see, e.g., [5, 3] for details. The most important ones are that $\mathcal{M}_0, \Gamma \models \varphi$ iff $\varphi \in \Gamma$, for each $\Gamma \in \mathcal{M}_0$ and each $\mathcal{L}$-formula $\varphi$, all substitution instances of axioms from §3.1 are valid in $\mathcal{M}_0$, and the first-order correspondents listed in §3.1 are true in the canonical frame $(W_0, \sqsubseteq_0, R_0)$. For example, $\sqsubseteq_0$ is transitive and $R_0$ is reflexive and transitive. All substitution instances of the connectedness axiom 5 are valid in $\mathcal{M}_0$, but we do not know that this axiom is valid in the canonical frame.

6.2 Model $\mathcal{M}_1$

Since $\varphi_0$ is consistent, we can take $\Gamma_0 \in W_0$ containing $\varphi_0$, and then $\mathcal{M}_0, \Gamma_0 \models \varphi_0$. So $\mathcal{M}_0$ satisfies $\varphi_0$. However, $\mathcal{M}_0$ is a little unwieldy for us. Much of it is irrelevant: it has smaller and more manageable submodels satisfying $\varphi_0$, and in particular, ones in which $\sqsubseteq$ is prelinear. So our first step is to restrict to such a submodel.

We define $\mathcal{M}_1 = (W_1, \sqsubseteq_1, R_1, h_1)$ to be the submodel of $\mathcal{M}_0$ with domain $W_1 = \{\Delta \in W_0 : \Delta \sqsubseteq_0 \Gamma_0 \lor \Gamma_0 \sqsubseteq_0 \Delta\}$. Let us establish its basic properties.

**Lemma 6.2.** $\mathcal{M}_1$ is a generated submodel of $\mathcal{M}_0$ in which $\sqsubseteq_1$ is prelinear. The model $\mathcal{M}_1$ satisfies $\varphi_0$.

**Proof.** Suppose $\Delta \in W_1$, $\Theta \in W_0$, and $\Delta \sqsubseteq_0 \Theta$. We show that $\Theta \in W_1$. If $\Gamma_0 \sqsubseteq_0 \Delta$ then by transitivity, $\Gamma_0 \sqsubseteq_0 \Theta$ and so $\Theta \in W_1$. If not, then $\Delta \not\sqsubseteq_0 \Gamma_0, \Theta$, and we obtain $\Theta \in W_1$ by the correspondent of the mirror image $PFp \rightarrow p \lor Fp \lor Pp$ of the linearity axiom. So $\mathcal{M}_1$ is a $\sqsubseteq_0$-generated submodel of $\mathcal{M}_0$. By symmetry, $\mathcal{M}_1$ is also a $\sqsubseteq_1$-generated submodel of $\mathcal{M}_0$. A similar argument, left to the reader, shows that $\sqsubseteq_1$ is prelinear as in definition 2.1(6).

To show that $\mathcal{M}_1$ is an $R_0$-generated submodel as well, note that if $\Delta \in W_1$, $\Theta \in W_0$, and $R_0 \Delta \Theta$, then by the correspondent of axiom 4a we have $\Theta \sqsubseteq_0 \Delta$ or $\Delta \sqsubseteq_0 \Theta$. As $W_1$ is $\sqsubseteq_0$- and $\sqsubseteq_1$-generated, $\Theta \in W_1$.

Hence, $\mathcal{M}_1$ is a generated submodel of $\mathcal{M}_0$. By lemma 2.3, $\mathcal{M}_1, \Gamma_0 \models \varphi_0$ and $\varphi_0$ is satisfied in $\mathcal{M}_1$. \qed

As $\mathcal{M}_1$ is a generated submodel of $\mathcal{M}_0$, lemma 2.3 tells us that all substitution instances of axioms from §3.1 are valid in $\mathcal{M}_1$ and all axioms other than the connectedness axiom 5 (and its mirror image) are valid in its frame. Hence, the first-order correspondents of these axioms are true in the frame of $\mathcal{M}_1$. The following is now immediate from lemma 5.5 (see also [28, lemma 3.6]).
LEMMA 6.3. Every $\sqsubseteq_1$-cluster in $M_1$ is an $R_1$-generated subset of $W_1$.

To end, we establish the perhaps surprising result that $M_1$ contains initial and final $\sqsubseteq_1$-clusters (possibly equal).

LEMMA 6.4. There are $\sqsubseteq_1$-clusters $C_\infty, C_{-\infty} \subseteq W_1$ such that $C_{-\infty} \sqsubseteq_1 \Gamma \sqsubseteq_1 C_\infty$ for every $\Gamma \in W_1$.

Proof. Let $\Lambda_0 = \{ P\varphi : \varphi$ is satisfied in $M_1 \}$. Then $\Lambda_0$ is consistent. For suppose that $n > 0$ is finite and $\varphi_0, \ldots, \varphi_{n-1}$ are satisfied in $M_1$ at $\Delta_0, \ldots, \Delta_{n-1}$, respectively. Choose $i < n$ such that $\{ j < n : \Delta_j \sqsubseteq_1 \Delta_i \}$ is maximal. It follows by prelinearity and transitivity of $\sqsubseteq_1$ that for every $j < n$ we have $\Delta_j \sqsubseteq_1 \Delta_i$. By lemma 3.2, $F\top \in \Delta_i$, so there is $\Gamma \in M_1$ with $\Delta_i \sqsubseteq_1 \Gamma$. Then $\Delta_0, \ldots, \Delta_{n-1} \sqsubseteq_1 \Gamma$, so $P\varphi_0, \ldots, P\varphi_{n-1} \in \Gamma$, proving consistency of $\Lambda_0$.

Let $\Lambda \supseteq \Lambda_0$ be maximal consistent. Then $\Lambda \in W_0$. Let $\Gamma \in W_1$ be arbitrary. Then $\varphi \in \Gamma \Rightarrow P\varphi \in \Lambda_0 \subseteq \Lambda$, so $\Gamma \sqsubseteq_0 \Lambda$. This means that $\Lambda \in W_1$ and that $\Lambda$ is a $\sqsubseteq_1$-greatest point in $M_1$. Hence also, $\Lambda \sqsubseteq_1 \Lambda$, so $\Lambda$ lies in a $\sqsubseteq_1$-cluster $C_\infty$, say, of $M_1$. Since $C_\infty$ is a cluster, transitivity of $\sqsubseteq_1$ yields that $\Gamma \sqsubseteq_1 C_\infty$ as required.

The cluster $C_{-\infty}$ is obtained by a mirror image argument. 

6.3 Model $M_2$

There is little hope of obtaining directly from $M_1$ a model over $\mathbb{R}$ satisfying $\varphi_0$. For one thing, if we could do it, it would be likely that any consistent set of formulas could be shown satisfiable over $\mathbb{R}$, contradicting theorem 4.2. The more practical problem is that we do not know enough about $\sqsubseteq_1$ and $R_1$. We can glean some information about them from lemma 5.5. Essentially, $M_1$ consists of $\sqsubseteq_1$-irreflexive points and $\sqsubseteq_1$-clusters. To make a real model, we would like to ‘represent’ each cluster $C$ over $\mathbb{R}$, using methods originating in [20] (see §7). Unfortunately, it is not clear that the frame $(C, R_1 \upharpoonright C)$ is connected. This makes the task hard — and in the $\Psi$-linked model that we aim to build, clusters must be connected.

The purpose of our next model $M_2$ is to make all $\sqsubseteq$-clusters connected. We achieve this by making them finite, using a certain filtration of $M_1$ due to Shetman [28, §3]. The connectedness axiom can then be used to prove that every $\sqsubseteq_2$-cluster in $M_2$ is connected. We will also show that $M_2$ contains certain well-behaved sub-models, which will be used to construct the final model $M_4$. So our study of $M_2$ will be quite elaborate.

6.3.1 Definition of $M_2$

We will need a finite set of formulas to define the filtration. It will be the set $\Psi$ of theorem 6.1 — a finite set of formulas containing $P\varphi_0$ and closed under taking subformulas. Our filtration equivalence relation is now defined as in [28, §3]. Recall again that $\Gamma \sqsupset \Delta$ means that $\Gamma \sqsubseteq \Delta$ and $\Delta \sqsubseteq \Gamma$. Let $\sim$ be the binary relation on $W_1$ defined by:

$$\Gamma \sim \Delta \iff \Gamma = \Delta \lor ((\Gamma \sqsupset \Delta) \land (\Gamma \sqcap \Psi = \Delta \sqcap \Psi)).$$

(6.1)

As $\sqsubseteq_1$ is transitive, $\sim$ is an equivalence relation on $W_1$. 

18
DEFINITION 6.5. For $\Gamma \in W_1$ we write $\Gamma/\sim$ for the equivalence class $\{\Delta \in W_1 : \Gamma \sim \Delta\}$. For $X \subseteq W_1$, we write $X/\sim$ for the set $\{\Gamma/\sim : \Gamma \in X\}$ of equivalence classes having a non-empty intersection with $X$.

Generally, but not always, $X$ will be $\sim$-closed (i.e., a union of $\sim$-classes).

The domain $W_2$ of $\mathcal{M}_2$ is now defined to be the set $W_1/\sim$ of $\sim$-equivalence classes in $\mathcal{M}_1$. The relations on $\mathcal{M}_2$ are: $\sqsubseteq_2$ is induced existentially from $\sqsubseteq_1$, and $R_2$ is the transitive closure of the relation induced existentially from $R_1$. Formally:

$$
\sqsubseteq_2 = \{ (\Gamma/\sim, \Delta/\sim) : \Gamma, \Delta \in W_1, \ \Gamma \sqsubseteq_1 \Delta \},
$$

$$
R_2^0 = \{ (\Gamma/\sim, \Delta/\sim) : \Gamma, \Delta \in W_1, \ \Gamma R_1 \Delta \},
$$

$R_2$ is the transitive closure of $R_2^0$.

We set $h_2(p) = \{ \Gamma/\sim : \Gamma \in W_1, \ p \in \Gamma \}$ for each atom $p \in PV$. This defines the model $\mathcal{M}_2$.

In case of doubt, we remark that the expressions above are of the form $\{ f(x) : x \in X \}$ for some set $X$ and some class function $f$ defined on $X$, and thus are well-defined sets by the axiom of replacement of ZF. For example, for $\sqsubseteq_2$ we can take $X = \sqsubseteq_1$ and $f : (\Gamma, \Delta) \mapsto (\Gamma/\sim, \Delta/\sim)$.

6.3.2 Filtration lemma for $\mathcal{M}_2$

Filtration is designed to preserve truth of formulas, so let us confirm this first. To begin, it is worth knowing that $\sqsubseteq_2$ is closely related to $\sqsubseteq_1$:

LEMMA 6.6. Let $\Gamma, \Delta \in W_1$. Then $\Gamma \sqsubseteq_1 \Delta \iff \Gamma/\sim \sqsubseteq_2 \Delta/\sim$.

Proof. If $\Gamma \sqsubseteq_1 \Delta$ then $\Gamma/\sim \sqsubseteq_2 \Delta/\sim$ by definition of $\sqsubseteq_2$. Conversely, if $\Gamma/\sim \sqsubseteq_2 \Delta/\sim$ then by definition of $\sqsubseteq_2$ there are $\Gamma', \Delta' \in W_1$ with $\Gamma \sim \Gamma'$, $\Delta \sim \Delta'$, and $\Gamma' \sqsubseteq_1 \Delta'$. The definition of $\sim$ gives $\Gamma \sqsubseteq_1 \Gamma'$ and $\Delta' \sqsubseteq_1 \Delta$, so $\Gamma \sqsubseteq_1 \Delta$ by transitivity of $\sqsubseteq_1$. □

In [28], a ‘filtration lemma’ is proved: all formulas in $\Psi$ are preserved from $\mathcal{M}_1$ to $\mathcal{M}_2$. Because of the simple definition of $\sqsubseteq_2$, we can actually go a little further:

LEMMA 6.7 (filtration). Let $\psi$ be an $\mathcal{L}$-formula formed from formulas in $\Psi$ by using only the boolean and temporal operators (without using $\Box$ or $\Diamond$). Then for all $\Gamma \in W_1$ we have $\mathcal{M}_2, \Gamma/\sim \models \psi$ iff $\mathcal{M}_1, \Gamma \models \psi$ (iff $\psi \in \Gamma$). Hence, $\varphi_0$ is satisfied in $\mathcal{M}_2$.

Proof. By induction on $\psi$. If $\psi \in \Psi$, the result is proved in [28, lemmas 3.2–3.3]. The boolean cases are easy and left to the reader. Assuming the result for $\psi$, we prove it for $G\psi$. Let $\Gamma \in W_1$ be given. Then the following are equivalent:

$$
\mathcal{M}_2, \Gamma/\sim \models G\psi
$$

$$
\mathcal{M}_2, \Delta/\sim \models \psi \text{ for all } \Delta \in W_1 \text{ with } \Gamma/\sim \sqsubseteq_2 \Delta/\sim \quad \text{by semantics of } G,
$$

$$
\mathcal{M}_1, \Delta \models \psi \text{ for all } \Delta \in W_1 \text{ with } \Gamma \sqsubseteq_1 \Delta \quad \text{by ind. hyp. & lemma 6.6},
$$

$$
\mathcal{M}_1, \Gamma \models G\psi \quad \text{by semantics of } G.
$$

The case $H\psi$ is similar.

We know there is some $\Gamma_0 \in W_1$ containing $\varphi_0$. As $\varphi_0 \in \Psi$, the above yields $\mathcal{M}_2, \Gamma_0/\sim \models \varphi_0$, so $\varphi_0$ is satisfied in $\mathcal{M}_2$. □
6.3.3 Structure of $\mathcal{M}_2$

We will need some simple facts about the form of $\mathcal{M}_2$. Happily, by [28, lemma 3.3], the frame of $\mathcal{M}_2$ validates all axioms of the system of §3.1 other than axiom 5 (connectedness) and its mirror image. Hence, their correspondents are true in the frame $(W_2, \Box_2, R_2)$, and lemma 5.5 applies.

Some limited instances of (connectedness and) the Prior axiom are also valid in $\mathcal{M}_2$:

**LEMMA 6.8.** Let $\beta$ be an $\mathcal{L}$-formula formed from formulas in $\Psi$ by using only the boolean and temporal operators (without using $\Box$ or $\Diamond$). Then the $\beta$-instance

$$\pi = F\beta \land FG\neg\beta \rightarrow F(G\neg\beta \land HF\beta)$$

of the Prior axiom is valid in $\mathcal{M}_2$.

**Proof.** Take any $w \in W_2$ and $\Gamma \in w$. By corollary 3.5, the Prior axiom is provable, so $\Gamma$ contains all substitution instances of it. So $\pi \in \Gamma$. This formula is made from formulas in $\Psi$ by using only the boolean and temporal operators, so by the filtration lemma 6.7 we obtain $\mathcal{M}_2, w \models \pi$ as required. \qed

However, in lemmas 6.12 and 6.20 we will need arbitrary instances of these axioms, and we do not know that they are valid in $\mathcal{M}_2$. They are of course valid in $\mathcal{M}_1$, so we will work in $\mathcal{M}_1$ in these lemmas.

**LEMMA 6.9.** 1. The relation $\Box_2$ is transitive and prelinear.

2. If $X \subseteq W_1$ is a $\Box_1$-cluster in $\mathcal{M}_1$ then $X/\sim$ is a $\Box_2$-cluster in $\mathcal{M}_2$.

3. If $C \subseteq W_2$ is a $\Box_2$-cluster in $\mathcal{M}_2$ then $\bigcup C$ is a $\Box_1$-cluster in $\mathcal{M}_1$.

4. Every $\Box_2$-cluster in $\mathcal{M}_2$ is a finite $R_2$-generated subset of $W_2$.

**Proof.** The relation $\Box_1$ is transitive (since $\mathcal{M}_1 \subseteq \mathcal{M}_0$ and $\Box_0$ is transitive), and prelinear (by lemma 6.2), and it follows from lemma 6.6 that $\Box_2$ is as well. This proves part 1.

For parts 2–3, let $X \subseteq W_1$ and $C \subseteq W_2$ be sets. Plainly, $X \subseteq \bigcup(X/\sim)$ and $C = (\bigcup C)/\sim$. Call $X$ a $\Box_1$-precluster if $\Gamma \Box_1 \Delta$ for every $\Gamma, \Delta \in X$, and $C$ a $\Box_2$-precluster if $c \Box_2 \Delta$ for every $c, \Delta \in C$. By lemma 6.6, parts 2 and 3 hold if we replace ‘cluster’ by ‘precluster’. A cluster is just a maximal precluster, and by Zorn’s lemma, every precluster extends to a cluster.

Suppose that $X$ is a $\Box_1$-cluster. Then $X/\sim$ is a $\Box_2$-precluster. Extend it to a $\Box_2$-cluster $D$. Then $X \subseteq \bigcup(X/\sim) \subseteq \bigcup D$, and since $\bigcup D$ is a $\Box_1$-precluster we have $X = \bigcup D$. So $X/\sim = (\bigcup D)/\sim = D$, a $\Box_2$-cluster.

Suppose that $C$ is a $\Box_2$-cluster. Then $\bigcup C$ is a $\Box_1$-precluster. Extend it to a $\Box_1$-cluster $Y$. Then $C = (\bigcup C)/\sim \subseteq Y/\sim$, and since $Y/\sim$ is a $\Box_2$-precluster we have $C = Y/\sim$. So $Y \subseteq \bigcup(Y/\sim) = \bigcup C \subseteq Y$. Consequently, $\bigcup C = Y$ is a $\Box_1$-cluster.

For part 4, let $C$ be a $\Box_2$-cluster. Then $C$ has the form $Y/\sim$ for a $\Box_1$-cluster $Y = \bigcup C$, and by definition of $\sim$, for each $\Gamma, \Delta \in Y$ we have $\Gamma \sim \Delta$ iff $\Gamma \cap \Psi = \Delta \cap \Psi$. Hence, the map $f : C \rightarrow \phi(\Psi)$ given by $f(\Gamma/\sim) = \Gamma \cap \Psi$ is well defined and one-one, so $|C| \leq |\phi(\Psi)|$ and $C$ is finite (this is [28, lemma 3.4]). That $C$ is $R_2$-generated follows from lemma 5.5. \qed
Lemma 6.4 also extends to $\mathcal{M}_2$:

**Lemma 6.10.** The sets $C_\infty/\sim, C_-\infty/\sim$ are $\sqsubseteq_2$-clusters in $\mathcal{M}_2$, and for every $w \in W_2$ we have $C_-\infty/\sim \sqsubseteq_2 w \sqsubseteq_2 C_\infty/\sim$.

*Proof.* Immediate from lemmas 6.4, 6.6, and 6.9. $\square$

### 6.3.4 Connectedness of $\sqsubseteq_2$-clusters in $\mathcal{M}_2$

By lemma 6.9, all $\sqsubseteq_2$-clusters in $\mathcal{M}_2$ are finite, and using the connectedness axiom, we can prove that they are connected as $R_2$-frames. To do this, we first write down formulas to define individual elements within a $\sqsubseteq_2$-cluster.

**Definition 6.11.** For $w \in \mathcal{M}_2$ let $\chi_w = \bigwedge (\Psi \cap \Gamma) \land \neg \bigvee (\Psi \setminus \Gamma)$ for arbitrary $\Gamma \in w$. (By convention, $\bigwedge \emptyset = \top$ and $\bigvee \emptyset = \bot$.)

By definition of $\sim$ in (6.1), this definition is independent of the choice of $\Gamma$, and obviously $\chi_w \in \Gamma$. The set $\{\chi_w : w \in \mathcal{M}_2\}$ is finite, because $\Psi$ is finite.

**Lemma 6.12.** Let $C$ be a $\sqsubseteq_2$-cluster in $\mathcal{M}_2$. Then $(C, R_2 \upharpoonright C)$ is a connected frame.

*Proof.* Suppose on the contrary that $C$ is a $\sqsubseteq_2$-cluster in $\mathcal{M}_2$ that is the union of disjoint non-empty $R_2$-generated sets $X, Y$. Let $\alpha = \bigvee_{w \in X} \chi_w$. Then $\alpha$ defines $X$ within $C$: for any $\Gamma \in \bigcup C$ we have

$$\alpha \in \Gamma \iff \Gamma/\sim \in X.$$  \hfill (6.2)

Choose any $\Gamma \in \bigcup C$ and let

$$\Delta_0 = \{\Diamond \alpha, \Diamond \neg \alpha\} \cup \{F\gamma, P\gamma : \gamma \in \Gamma\}.$$

We show that $\Delta_0$ is consistent. Since $\Gamma$ is closed under conjunction, it suffices to take arbitrary $\gamma \in \Gamma$ and show that $\delta = \Diamond \alpha \land \Diamond \neg \alpha \land F\gamma \land P\gamma$ is consistent. Choose any $\Gamma_X \in \bigcup X$ and $\Gamma_Y \in \bigcup Y$. By lemma 6.9, $\bigcup C$ is a $\sqsubseteq_1$-cluster in $\mathcal{M}_1$. So $\Gamma_X \sqsubseteq_1 \Gamma_Y$ and similarly for $\Gamma_Y$. Now $\alpha \land F\gamma \in \Gamma_X$ and $\neg \alpha \land F\gamma \in \Gamma_Y$. So $F(\alpha \land F\gamma), F(\neg \alpha \land F\gamma) \in \Gamma$. By the connectedness axiom 5, $F(\Diamond \alpha \land \Diamond \neg \alpha \land F\gamma) \in \Gamma$. By temporal axioms, $GP\gamma \in \Gamma$ as well, so $F\delta \in \Gamma$. If $\delta$ is inconsistent then $\neg \delta$ and hence $G \neg \delta$ are provable, so $G \neg \delta \in \Gamma$, contradicting its consistency. So $\delta$ is consistent, as required.

So we may take $\Delta \in \mathcal{M}_0$ with $\Delta \supseteq \Delta_0$. By definition of $\Delta_0$ we have $\Delta \sqsupseteq \Delta_0$, so $\Delta \in \mathcal{M}_1$ and $\Delta \in \bigcup C$. As $\Diamond \alpha, \Diamond \neg \alpha \in \Delta$, we may find $\Delta_X, \Delta_Y \in R_0(\Delta)$ with $\alpha \in \Delta_X$ and $\neg \alpha \in \Delta_Y$. Then $\Delta_X, \Delta_Y \in R_1(\Delta)$ as $\mathcal{M}_1$ is a generated submodel of $\mathcal{M}_0$. By lemma 6.3, $\bigcup C$ is an $R_1$-generated subset of $\mathcal{M}_1$, so $\Delta_X, \Delta_Y \in \bigcup C$ as well.

Let $w = \Delta/\sim$, $w_X = \Delta_X/\sim$, and $w_Y = \Delta_Y/\sim$. By (6.2), $w_X \in X$ and $w_Y \in Y$. By definition of $R_2$, we have $w_X, w_Y \in R_2(w)$. Since $w \in X \cup Y$, this contradicts that $X$ and $Y$ are disjoint and $R_2$-generated. $\square$
6.3.5 Submodels of $M_2$

It may appear that $M_2$ could be our final Kripke model. Each $\sqsubseteq_2$-cluster $C$ in $M_2$ is finite and connected as an $R_2$-frame, so classical work (see §7) will give us a model over $\mathbb{R}$ respecting truth within $C$. We can represent an $\sqsubseteq_2$-irreflexive point of $M_2$ by a single point of $\mathbb{R}$. Could we not string these together somehow, to make a model over $\mathbb{R}$ satisfying $\varphi_0$?

To do so would require the following. Let $J$ be the linear order obtained from $(W_2, \sqsubseteq_2)$ by replacing each $\sqsubseteq_2$-cluster by a copy of $\mathbb{R}$. Then we would need $J \cong \mathbb{R}$.

There is no reason to suppose that $J \cong \mathbb{R}$. For example, $M_2$ may have uncountably many $\sqsubseteq_2$-clusters. (Indeed, the argument of theorem 4.2 can be used to create an example in which $J \not\cong \mathbb{R}$.) Even a finite submodel of $M_2$ may not work: if we form $J$ for it as we did for $M_2$, we may still not have $J \cong \mathbb{R}$, because the submodel may have consecutive $\sqsubset$-clusters that are actually adjacent, with no intervening point.

Consideration of the formula $\theta$ of (4.2) shows that this can indeed happen. Replacing the two adjacent clusters by copies of $\mathbb{R}$ gives a linear order isomorphic to $((-1,0) \cup (0,1), \prec)$. This is not Dedekind complete — it has a ‘gap’ at 0. It follows that $J \not\cong \mathbb{R}$ in this case.

In $\Psi$-linked models, any two adjacent clusters contain ‘similar’ points satisfying exactly the same formulas $\Box \psi, G\psi, H\psi \in \Psi$. They allow us to ‘fill the gap’. So we will now show that $M_2$ contains abundant finite submodels with this property. This is in a sense the heart of the paper. It will lead us shortly to our final model $M_4$.

First we introduce formulas that will help us to pick out ‘similar’ points. Recall (definition 5.3) that $B\Psi$ is the set of all formulas in $\Psi$ of the form $\Box \psi$, $G\psi$, or $H\psi$ (the ‘box-formulas’).

**DEFINITION 6.13.**

1. For a subset $B \subseteq B\Psi$, let $\beta_B = (\land B) \land \neg(\lor (B\Psi \setminus B))$.

2. For a Kripke model $M$ and $w \in M$, we write $\tau_M(w)$ (or if no ambiguity is likely, $\tau(w)$) for the set $\{\psi \in B\Psi : M, w \models \beta\}$.

We think of $\tau_M(w)$ as the ‘type’ of $w$ in $M$. The following is proved by standard boolean manipulations.

**LEMMA 6.14.**

1. For every Kripke model $M$ and $w \in M$, the set $\tau_M(w)$ is the unique subset $B \subseteq B\Psi$ with $M, w \models \beta_B$.

2. For every $\Gamma \in W_1$, the set $\tau_{M_1}(\Gamma)$ is the unique subset $B \subseteq B\Psi$ such that $\beta_B \in \Gamma$. Indeed, $\tau_{M_1}(\Gamma) = \Gamma \cap B\Psi$.

3. For every Kripke model $M$ and $c, d \in M$, we have $c \equiv_{B\Psi}^M d$ (so $c$ and $d$ are ‘similar’) iff $\tau_M(c) = \tau_M(d)$.

So to show that two clusters $C, D$ contain similar points, it suffices to find points $c \in C$ and $d \in D$ of the same type — satisfying the same formula $\beta_B$ for some $B \subseteq B\Psi$. We will use the Prior axiom to do this. However, because this axiom delivers an $\sqsubseteq$-irreflexive point after which a formula is false but at which the formula may actually be true (see remark 3.6), whereas we want a point in a cluster, we will actually use $\Box \beta_B$ rather than $\beta_B$. 22
Not every world in a model satisfies some $\Box \beta_B$, so (roughly) we now pick out the worlds that do. We will call such worlds \textit{links}, because they will ‘link’ adjacent clusters.

We would like to define $w \in W_2$ to be a link if $\mathcal{M}_2, w \models \Box \beta_B$ for some $B$. Unfortunately, there is a second complication. We would like to use the Prior axiom to find a point satisfying some $\Box \beta_B$. But we do not know that the $\Box \beta_B$-instance of the Prior axiom is valid in $\mathcal{M}_2$. Moreover, the point should also lie in a certain temporal range, and to achieve this we will need to work in $\mathcal{M}_1$, where $\Box_1$ is defined by formulas. Now the Prior axiom is valid in $\mathcal{M}_1$, and it will deliver points of $\mathcal{M}_1$ in the right range and satisfying $\Box \beta_B$, but their ‘representatives’ (their $\sim$-classes) in $\mathcal{M}_2$ may not satisfy $\Box \beta_B$ as the filtration lemma 6.7 does not apply to $\Box \beta$. Consequently, with this definition of ‘link’ we cannot guarantee that adjacent clusters will contain ‘similar’ points. So in the formal definition of ‘link’, we work directly in $\mathcal{M}_1$:

\textbf{DEFINITION 6.15.} An element $w \in W_2$ is said to be a \textit{link} if $\Box \beta_B \in \bigcup w$ for some $B \subseteq \mathcal{B} \Psi$ — that is, there are $\Gamma \in w$ and $B \subseteq \mathcal{B} \Psi$ with $\Box \beta_B \in \Gamma$.

We first show that links are rather common, and that they work well enough to deliver ‘similar’ points.

\textbf{LEMMA 6.16.} Every $\sqcap_2$-cluster in $\mathcal{M}_2$ contains a link.

\textit{Proof.} Let $C$ be a $\sqcap_2$-cluster in $\mathcal{M}_2$. By lemma 6.9(4), $C$ is finite and $R_2$-generated. Let $c \in C$ be such that $|R_2(c)|$ is least possible. We will show that $c$ is a link.

Let $B = \tau(c)$. First we show that $\mathcal{M}_2, c \models \Box \beta_B$. So take arbitrary $d \in R_2(c)$. As $C$ is $R_2$-generated, $d \in C$. By transitivity of $R_2$ we have $R_2(d) \subseteq R_2(c)$, so by choice of $c$ we have $R_2(d) = R_2(c)$. Moreover, since $c \sqcap_2 d$, by transitivity of $\sqcap_2$ we see that for all $w \in W_2$ we have $w \sqcap_2 c$ iff $w \sqcap_2 d$, and $w \sqsupseteq_2 c$ iff $w \sqsupseteq_2 d$. So $c$ and $d$ ‘see’ the same elements of $W_2$ via $R_2$, $\sqcap_2$, and $\sqsupseteq_2$. It plainly follows that $c \equiv_{\mathcal{B} \Psi} d$, so $B = \tau(c) = \tau(d)$ and hence $\mathcal{M}_2, d \models \beta_B$ as well. As $d$ was arbitrary, $\mathcal{M}_2, c \models \Box \beta_B$ as required.

Now let $\Gamma \in c$ be arbitrary; we will show that $\Box \beta_B \in \Gamma$, so that $c$ is a link by definition. Let $\Delta \in R_1(\Gamma)$ be arbitrary, and let $d = \Delta/\sim \in W_2$. By definition of $R_2$ we have $d \in R_2(c)$, so by the above, $\mathcal{M}_2, d \models \beta_B$. As $\beta_B$ is a boolean combination of formulas in $\Psi$, the filtration lemma 6.7 yields $\beta_B \in \Delta$. As $\Delta$ was arbitrary, we obtain $\Box \beta_B \in \Gamma$. \hfill $\square$

\textbf{LEMMA 6.17.} Let $B \subseteq \mathcal{B} \Psi$ and $w \in \mathcal{M}_2$. Then $\Box \beta_B \in \bigcup w$ iff $w$ is a link and $\tau(w) = B$.

\textit{Proof.} If $\Box \beta_B \in \Gamma \in w$, then $w$ is plainly a link. By the S4 reflexivity axiom, $\beta_B \in \Gamma$ as well. By the filtration lemma 6.7, $\mathcal{M}_2, w \models \beta_B$, so by lemma 6.14, $\tau(w) = B$.

Conversely, suppose that $w$ is a link. By definition, $\Box \beta_B \in \bigcup w$ for some $B' \subseteq \mathcal{B} \Psi$. By the first part, $\tau(w) = B'$. So if additionally $\tau(w) = B$, we have $B' = B$ and hence $\Box \beta_B \in \bigcup w$. \hfill $\square$

We will need to count the types of links in an interval:
DEFINITION 6.18. For $\Box_2$-clusters $C, D \subseteq M_2$ with $C \sqsubseteq_2 D$ (possibly, $C = D$), let

$$\sharp(C, D) = |\{\tau_{M_2}(w) : w \in W_2 \text{ a link, } C \sqsubseteq_2 w \land w \sqsubseteq_2 D\}|.$$ 

The value is plainly finite, because $B\Psi$ is finite. It is the number of types of links in the interval $(C, D)$ of $M_2$.

COROLLARY 6.19. Let $C, D \subseteq M_2$ be $\Box_2$-clusters with $C \sqsubseteq_2 D$. Then we have $\sharp(C, D) > 0$.

**Proof.** By lemma 6.16, there is a link $w \in C$. Plainly, $C \sqsubseteq_2 w \sqsubseteq_2 D$. So $\tau(w)$ contributes one to the total for $\sharp(C, D)$, which is therefore nonzero. □

Suppose that $(C, D)$ is a pair of adjacent $\Box_2$-clusters in $M_2$. Using lemma 6.16, take links $c \in C$ and $d \in D$. Imagine that $\sharp(C, D) = 1$. As $\tau(c)$ and $\tau(d)$ both contribute one to $\sharp(C, D)$, we must have $\tau(c) = \tau(d)$, and it follows that $c \equiv_{B\Psi} d$.

We have found similar points in $C, D$, as required for a $\Psi$-linked model. This suggests trying to find similar points in more general situations by induction on $\sharp(C, D)$, and that is what we will do in lemma 6.22 below. For the induction step, we will need the following important technical lemma. Part 3 of the lemma shows that the value of $\sharp$ drops, facilitating the induction.

LEMMA 6.20. Let $C$ be a $\Box_2$-cluster in $M_2$, and let $w \in M_2$ with $C \sqsubseteq_2 w$ and $w \notin C$. Then there is a $\Box_2$-irreflexive $u \in M_2$ such that:

1. $C \sqsubseteq_2 u \sqsubseteq_2 w$,
2. there are $c \in C$ and $d \in \lambda(u)$ with $c \equiv_{M_2} d$,
3. if $w$ is $\Box_2$-irreflexive and $u \sqsubseteq_2 w$, then $\sharp(\rho(u), \lambda(w)) < \sharp(C, \lambda(w))$.

(See lemma 5.5 for $\lambda, \rho$.) The mirror image also holds.

**Proof.** By lemma 6.16, there is a link $c \in C$. Let $B = \tau(c)$. By lemma 6.17, there is $\Gamma \subseteq c$ with $\Box \beta_B \in \Gamma$.

Now pick any $\Delta \in w$. Since $C \sqsubseteq_2 w \notin C$, by lemma 6.6 we have $\Gamma \sqsubseteq_1 \Delta$ and $\neg(\Delta \sqsubseteq_1 \Gamma)$. By the latter, there is a formula $\gamma$ with

$$\gamma \in \Gamma \text{ and } G\neg\gamma \in \Delta. \quad (6.3)$$

If $w$ is $\Box_2$-irreflexive, then $\Delta$ is $\Box_1$-irreflexive, and in that case, as the reader may confirm, we can suppose that $H\gamma \in \Delta$ as well.

So $\gamma \land \Box \beta_B \in \Gamma$ and $G\neg(\gamma \land \Box \beta_B) \in \Delta$. As $\Gamma$ is in a $\Box_1$-cluster ($\bigcup C$), we have $\Gamma \sqsubseteq_1 \{\Gamma, \Delta\}$, so $F(\gamma \land \Box \beta_B) \land FG\neg(\gamma \land \Box \beta_B) \in \Gamma$. Now by corollary 3.5, the Prior axiom is provable, so its instance $F(G\neg(\gamma \land \Box \beta_B) \land HF(\gamma \land \Box \beta_B))$ is in $\Gamma$. This lets us take $\Theta \equiv_1 \Gamma$ in $M_1$ with

$$G\neg(\gamma \land \Box \beta_B) \land HF(\gamma \land \Box \beta_B) \in \Theta. \quad (6.4)$$

It follows from (6.4) that $\Theta$ is $\Box_1$-irreflexive. Let $u = \Theta/\sim$. By lemma 6.6, $u$ is $\Box_2$-irreflexive. Since $\Gamma \sqsubseteq_1 \Theta$, we have $C \sqsubseteq_2 u$. (So by lemma 5.5, $C \sqsubseteq_2 \lambda(u)$; note
that $C = \lambda(u)$ is possible.) Since $HF\gamma \in \Theta$ but $G\gamma \in \Delta$, we see that $\Delta \not\subseteq \Theta$. By prelinearity, $\Theta \subseteq \Delta$, so $u \cup w$. This proves part 1 of the lemma.

It follows from (6.4) and lemma 3.3 that $\diamond (\gamma \wedge \Box \beta_B) \in \Theta$. So we may choose $\Theta' \in R_1(\Theta)$ containing $\gamma \wedge \Box \beta_B$. There are two possibilities, the first being the reason why we need to use $\Box \beta_B$ rather than just $\beta_B$. If $\Theta' = \Theta$, choose arbitrary $\Xi \in R_1(\Theta)$ with $\Xi \subseteq \Theta$ (there is such a $\Xi$ by the mirror image of axiom 4d). By transitivity of $R_1$ we have $\Box \beta_B \in \Xi$. Alternatively, if $\Theta' \neq \Theta$, then by (6.4) we have $\neg ((\Theta \subseteq \Theta')$, and prelinearity of $\theta_1$ gives $\Theta' \subseteq \Theta$. In that case let $\Xi = \Theta'$. Again we have $\Box \beta_B \in \Xi$.

Let $d = \Xi / \sim$. Then $d \in \lambda(u)$. By lemma 6.17, $\tau(d) = B = \tau(c)$. By lemma 6.14, $c \equiv_{M_2}^{M_2} d$. This proves part 2 of the lemma.

For part 3, suppose that $w$ is $\subseteq$-irreflexive and $u \subseteq w$, so that $\rho(u) \subseteq \lambda(w)$ by lemma 5.5 (possibly $\rho(u) = \lambda(w)$). We have $H\gamma \in \Delta$ in this case, and by (6.4), $G\gamma \in \Delta$. It follows that $\Box \beta_B \not\in \Xi$ for every $\Xi \in \Xi' \subseteq \Delta$. As $\sim / w = u$ and $\Delta / \sim = w$, by lemmas 6.6 and 6.17 there is no link $v$ with $\tau(v) = B$ and $u \subseteq v \subseteq w$ — equivalently, with $\rho(u) \subseteq \lambda(w)$ (see lemma 5.5). So

$$\{\tau(v) : v \in W_2 \text{ a link}, \rho(u) \subseteq v \subseteq \lambda(w)\} \subseteq \{\tau(v) : v \in W_2 \text{ a link}, C \subseteq v \subseteq \lambda(w)\} \setminus \{B\}.$$  

Since there certainly is a link $v$ of type $B$ with $C \subseteq v \subseteq \lambda(w)$ — for example, $v = c$ — we see that $\sharp(\rho(u), \lambda(w)) < \sharp(C, \lambda(w))$.  

We remark that $\gamma$ in (6.3) may be very complex and the instance of the Prior axiom used to obtain (6.4) may not be valid in $M_2$. That is why we work in $M_1$.

**DEFINITION 6.21.** Let $M = (W, \subseteq, R, h)$ be a submodel of $M_2$.

1. We say that $M$ is good if it is finite, $R_2$-generated, and every $\subseteq$-cluster in $M$ is a $\subseteq$-cluster in $M_2$.

2. We say that $M$ is perfect if it is good, and for every pair $(C, D)$ of adjacent $\subseteq$-clusters in $M$, there are $c \in C$ and $d \in D$ with $c \equiv_{M_2}^{M_2} d$.

Note that we use $\equiv_{M_2}^{M_2}$ and not $\equiv_{M_2}^M$ here. We will convert to $\equiv_{M_2}^M$ in §6.4 but we will need a little more machinery for that.

**LEMMA 6.22.** Every good submodel of $M_2$ extends to a perfect submodel of $M_2$.

**Proof.** Let us say that a defect in a good submodel $M = (W, \subseteq, R, h)$ of $M_2$ is a pair $(C, D)$ of adjacent $\subseteq$-clusters in $M$ such that there do not exist $c \in C$, $d \in D$ with $c \equiv_{M_2}^{M_2} d$. Again, we use $M_2$ here, not $M$. Let

$$d(M) = \sum \{\sharp(C, D) : (C, D) \text{ a defect of } M\}.$$  

Then $d(M) \geq 0$, and $d(M)$ is finite because $M$ is.

Now let $M = (W, \subseteq, R, h)$ be an arbitrary good submodel of $M_2$. Among all good submodels $M^* = (W^*, \subseteq^*, R^*, h^*)$ with $M \subseteq M^* \subseteq M_2$, choose one with $d(M^*)$ as
small as possible. We will show that \( d(M^*) = 0 \). Since by corollary 6.19, \( \#(C, D) > 0 \) for every defect \((C, D)\), it follows that \( M^* \) has no defects and is therefore perfect.

Assume for contradiction that \( d(M^*) > 0 \). Pick any defect \((C, D)\) in \( M^* \) and any \( w \in D \). As \( M^* \subseteq M_2 \), we have \( C \sqsubseteq_w w \) and \( \neg(w \sqsubseteq_w C) \). Let \( u \in M_2 \) be as provided by lemma 6.20, and let \( N \) be the submodel of \( M_2 \) consisting of \( M^* \) together with \( R_2(u) \). We let \( \sqsubseteq \) denote \( \sqsubseteq_w \ | N \). So

\[
\{ v \in N : C \sqsubseteq v \sqsubseteq D \} = C \cup \lambda(u) \cup \{ u \} \cup \rho(u) \cup D,
\]

shown left to right in \( \sqsubseteq \)-order. (Possibly, \( \lambda(u) = C \) or \( \rho(u) = D \) or both.) Plainly, \( N \) is good and \( M \subseteq N \subseteq M_2 \). So by choice of \( M^* \) we have \( d(N) \geq d(M^*) \).

Now outside the range \( C-D \) shown in (6.5), all defects and their \( \sharp \)-values are the same in \( M^* \) and \( N \). (Remember that \( \sharp \) is evaluated with respect to \( M_2 \).) So let us consider the remaining potential defects in \( N \). From inspection of (6.5), these are \((C, \lambda(u)))\) and \((\rho(u), D))\). (Note that \((\lambda(u), \rho(u)))\) is not a defect since it is not a pair of adjacent clusters: \( u \) is \( \sqsubseteq \)-irreflexive and \( \lambda(u) \sqsubseteq u \sqsubseteq \rho(u) \).

The pair \((C, \lambda(u)))\) is not a defect, because lemma 6.20 provides that \( C \) and \( \lambda(u) \) contain \( \equiv_{B^w} \)-equivalent points (possibly even \( C = \lambda(u))\).

So because \( d(N) \geq d(M^*) \), we see that \((\rho(u), D))\) must be a defect in \( N \) and moreover that \( \sharp(\rho(u), D) \geq \sharp(C, D))\).

But since \( C \sqsubseteq \rho(u) \), we have \( \rho(u) \sqsubseteq_t t \sqsubseteq D \Rightarrow C \sqsubseteq_t t \sqsubseteq D \) for all \( t \in W_2 \), so every link type contributing to \( \sharp(\rho(u), D) \) also contributes to \( \sharp(C, D))\). Hence, \( \sharp(\rho(u), D) \leq \sharp(C, D)) \). So in fact, \( \sharp(\rho(u), D) = \sharp(C, D) \) and \( d(N) = d(M^*) \).

Now \( u \) is irreflexive, so \( u \sqsubseteq D \) and \( \neg(D \sqsubseteq u) \). Applying the mirror image of lemma 6.20, we obtain irreflexive \( v \in M_2 \) with \( u \sqsubseteq v \sqsubseteq D \), where \( \rho(v) \) and \( D \) contain \( \equiv_{B^w} \)-equivalent points. But \( \rho(u) \) and \( D \) do not contain \( \equiv_{B^w} \)-equivalent points, since \((\rho(u), D)\) is a defect in \( N \). It follows that \( u \neq v \). We conclude that \( u \sqsubseteq v \sqsubseteq D \).

Let \( N' \) be the submodel of \( M_2 \) consisting of \( N \) together with \( R_2(v) \). We let \( \sqsubseteq \) denote \( \sqsubseteq_w \ | N' \). So

\[
\{ v \in N' : \rho(u) \sqsubseteq v \sqsubseteq D \} = \rho(u) \cup \lambda(v) \cup \{ v \} \cup \rho(v) \cup D,
\]

again shown left to right in \( \sqsubseteq \)-order. (Possibly, \( \rho(u) = \lambda(v) \) or \( \rho(v) = D \) or both.) Outside the range \( \rho(u)\)-\( D \) shown in (6.6), \( N' \) has the same defects as \( N \). Within this range, the possible defects in \( N' \) are \((\rho(u), \lambda(v)))\) and \((\rho(v), D))\). Lemma 6.20 provides that \((\rho(v), D)\) is not a defect in \( N' \) and that \( \sharp(\rho(u), \lambda(v))) < \sharp(\rho(u), D)) \). It follows that \( d(N') < d(N) = d(M^*) \). Since again, \( N' \) is good and \( M \subseteq N' \subseteq M_2 \), this contradicts the minimality of \( d(M^*) \), and completes the proof.

\[\square\]

**6.4 Models \( M_3 \) and \( M_4 \)**

Our final model \( M_4 \) will be a perfect submodel of \( M_2 \) obtained by lemma 6.22 from a good submodel \( M_3 \) satisfying \( \varphi_0 \) that we have to construct first. So we do a selective filtration of \( M_2 \) to deliver our first verifiably finite model: an \( R_2 \)-generated submodel \( M_3 \) of \( M_2 \) satisfying \( \varphi_0 \). We select the points of \( M_2 \) to include in \( M_3 \) in three steps.
1. Select the whole of $C_\infty/\sim$ and $C_{-\infty}/\sim$, which by lemma 6.10 are finite $\square_2$-clusters and $R_2$-generated subsets of $W_2$, and add them to $M_3$.

2. Now consider in turn each $\psi \in \Psi$ (if any) such that $F_\neg\psi \land FG\psi$ is satisfied in $M_2$. Here, $\Psi$ is as in theorem 6.1. Choose any $w \in W_2$ with $M_2, w \models F_\neg\psi \land FG\psi$. By lemma 6.8, $M_2, w \models F(G_\psi \land HF_\neg\psi)$, so choose $u \in W_2$ with $M_2, u \models G_\psi \land HF_\neg\psi$ (and with $u \supseteq w$). Select the whole finite set $R_2(u)$ and add it to $M_3$.

3. Also do the mirror image of step 2.

Clearly, $M_3$ is a non-empty good submodel of $M_2$. So by lemma 6.22, we may choose a perfect model $M_4$ with $M_3 \subseteq M_4 \subseteq M_2$. We have arrived at our final model. We show first that truth of formulas in $\Psi$ is preserved between it and $M_2$.

**Lemma 6.23.** For every $w \in W_4$ and $\psi \in \Psi$ we have $M_4, w \models \psi$ iff $M_2, w \models \psi$.

**Proof.** The proof is by induction on $\psi$. The argument is fairly standard for selective filtration. If $\psi$ is atomic, it is true because $M_4$ is a submodel of $M_2$, and the boolean cases are straightforward (note here and below that $\Psi$ is closed under subformulas, so the inductive hypothesis applies to subformulas of $\psi$). The case $\square_2\psi$ is also straightforward, because $M_4$ is an $R_2$-generated submodel of $M_2$. The main cases are formulas in $\Psi$ of the form $G_\psi$ and $H_\psi$. Then $\psi \in \Psi$; inductively assume the result for $\psi$.

If $M_2, w \models G_\psi$, take arbitrary $u \supseteq w$ in $M_4$. Then $u \supseteq w$ because $M_4 \subseteq M_2$. So $M_2, u \models \psi$. Inductively, $M_4, u \models \psi$. Since $u$ was arbitrary, $M_4, w \models G_\psi$.

Assume now that $M_2, w \models \neg G_\psi$ — i.e., $M_2, w \models F_\neg\psi$. It suffices to find $v \in W_3$ with $w \subsetneq v$ and $M_2, v \models \neg \psi$. For then, we have $v \in W_4$ (since $W_3 \subseteq W_4$), $w \subsetneq v$ (since $M_4 \subseteq M_2$), and $M_4, v \models \neg \psi$ (by the inductive hypothesis). So $v$ is a witness to $M_4, w \models \neg G_\psi$.

There are two cases. The first is when $M_2, w \models GF_\neg\psi$. By lemma 6.10, for every $u \in C_\infty/\sim$ we have $u \supseteq w$, so $M_2, u \models F_\neg\psi$ and there is $v \in W_2$ with $v \supseteq u$ and $M_2, v \models \neg \psi$. By lemma 6.10, $v \in C_\infty/\sim$ as well. So by construction, $v \in W_3$, and by transitivity, $w \subsetneq v$ as required.

The second case is when $M_2, w \models F_\neg\psi \land FG_\psi$. By definition of $M_3$, there is $u \in W_2$ with $M_2, u \models G_\psi \land HF_\neg\psi$ and $R_2(u) \subseteq W_3$. If $w \supseteq u$ then $M_2, w \models G_\psi$, a contradiction. So by prelinearity, $w \subsetneq u$. By lemma 6.3, $G_\psi \land HF_\neg\psi \rightarrow \Diamond \neg \psi$ is provable in the system without using the connectedness axiom (or its mirror image). Since all axioms required for the proof are valid in the frame of $M_2$, and the inference rules preserve frame validity, we see that $G_\psi \land HF_\neg\psi \rightarrow \Diamond \neg \psi$ is valid in $M_2$ and so $M_2, u \models \Diamond \neg \psi$. Choose $v \in R_2(u)$ with $M_2, v \models \neg \psi$. Then $v \in W_3$ (since $R_2(u) \subseteq W_3$). As $w \subsetneq u$ then $R_2 v$, by axiom 4b we have $w \subsetneq v$, as required.

So in either case, $M_4, w \models \neg G_\psi$ as required. The case of $H_\psi$ is handled similarly. This completes the induction. \[\square\]

Our final lemma establishes the main theorem 6.1:

**Lemma 6.24.** The model $M_4$ is $\Psi$-linked, and $\varphi_0$ is satisfied in $M_4$. 

27
Proof. We refer to definition 5.4 for the meaning of ‘Ψ-linked’. Plainly, \( W_4 \) is finite. We check that the frame \((W_4, \sqsubseteq_4, R_4)\) of \( M_4 \) validates all axioms of §3.1 excluding the connectedness axiom 5 and its mirror image. All these axioms are valid in the frame of \( M_2 \), so their first-order correspondents are true in this frame. The correspondents of all axioms except temporal density and axiom 4d are universal first-order sentences, and so remain true in the frame of \( M_4 \) which is a substructure of the frame of \( M_2 \). The correspondent of axiom 4d is preserved by \( R \)-generated subframes and so remains true in the frame of \( M_4 \). \( M_4 \) consists of \( \sqsubseteq_4 \)-clusters sometimes interspersed by single irreflexive points. It is plain from this that \( \sqsubseteq_4 \) is dense, so the density axiom is valid in the frame.

Since \( M_4 \subseteq M_2 \), and \( \sqsubseteq_2 \) is prelinear (by lemma 6.9), \( \sqsubseteq_4 \) is prelinear too.

Let \( C \subseteq W_4 \) be a \( \sqsubseteq_4 \)-cluster. Since \( M_4 \) is good, \( C \) is also a \( \sqsubseteq_2 \)-cluster of \( M_2 \). By lemma 6.12, the frame \((C, R_2 \upharpoonright C)\) is connected. But this frame is \((C, R_4 \upharpoonright C)\), since \( M_4 \subseteq M_2 \). So \((C, R_4 \upharpoonright C)\) is connected.

As \( M_4 \) is perfect, for every pair \((C, D)\) of adjacent \( \sqsubseteq_4 \)-clusters there are \( c \in C \) and \( d \in D \) with \( c \equiv_{M_4}^d \). By lemma 6.23, \( c \equiv_{M_2}^d \) as well. So \( M_4 \) is \( \Psi \)-linked.

By lemma 6.7, \( \varphi_0 \) is satisfied in \( M_2 \). Pick any \( w \in C_\infty/\sim \). Then \( M_2, w \vDash P\varphi_0 \). Recall that \( P\varphi_0 \in \Psi \). Then \( w \in W_4 \) and by lemma 6.23, \( M_4, w \vDash P\varphi_0 \). It follows that \( \varphi_0 \) is satisfied in \( M_4 \).

\( \square \)

7 From linked models to real models

In §§7.1–7.3 we provide a simple way to build maps defined on intervals of \( \mathbb{R} \). As far as we know, the method essentially originates in [4]. We will use it in §7.4 to ‘represent’ any connected S4-frame over \( \mathbb{R} \), and in §7.5 to ‘represent’ any \( \Psi \)-linked Kripke model over \( \mathbb{R} \) in a way that respects the formulas in \( \Psi \). An example of the construction for the formula \( \theta \) of (4.2) will be given in §7.6.

Linear orders, intervals, and other related notions were introduced in §2.5. In particular, recall that we often write a linear order \((I, <)\) simply as \( I \). In this section, we will write ordered pairs in the form \( \langle i, j \rangle \) where they might be confused with intervals.

7.1 Lexicographic sums of linear orders

Let \((J, <)\) be a linear order, and for each \( j \in J \) let \( I_j \) be an interval of \( \mathbb{R} \). (More generally, \( I_j \) can be any linear order, but we are concerned only with the case of intervals of \( \mathbb{R} \).) We write

\[
I = \sum_{j \in J} I_j = \{\langle i, j \rangle : j \in J, \ i \in I_j\},
\]

and define an order \( < \) on \( I \) lexicographically by \( \langle i, j \rangle < \langle i', j' \rangle \) iff \( j < j' \) or \( j = j' \) and \( i < i' \). Clearly, \((I, <)\) is a linear order. It can be thought of as the linear order obtained from \((J, <)\) by replacing each \( j \in J \) by a copy of \( I_j \). If \((J, <) = \{(0, 1, \ldots, n), <\}\) for some \( n \in \mathbb{N} \), we can write \( I \) explicitly as \( I_0 + \cdots + I_n \). It can be thought of as a copy of \( I_0 \) followed by copies of \( I_1, \ldots, I_n \) in order.
When $J = \{0, 1\}$, it is plain that if $I_0$ has a greatest element and $I_1$ has no least element, or if $I_0$ has no greatest element and $I_1$ has a least element, then $I_0 + I_1$ is order-isomorphic to an interval of $\mathbb{R}$. For example, $(0, 1] + (0, 1] \cong (0, 1) + [0, 1] \cong (0, 1]$. More generally:

**Proposition 7.1.** Suppose that one of the following holds.

1. $J$ is finite, say $(J, <) = (\{0, 1, \ldots, n\}, <)$ for some $n \in \mathbb{N}$. $I_0$ has no least or greatest element. Each $I_j$ for $j > 0$ has a least element but no greatest element.

2. $(J, <) = (\mathbb{Z}, <)$, each $I_j$ ($j$ odd) has no least or greatest element, and each $I_j$ ($j$ even) is a singleton.

3. $(J, <) = (\mathbb{R}, <)$, each $I_j$ has a least and a greatest element, and $I_j$ is a singleton for every irrational $j$.

Then $(\sum_{j \in J} I_j, <) \cong (\mathbb{R}, <)$.

**Proof (sketch).** A linear order is isomorphic to $(\mathbb{R}, <)$ iff it is dense, has no endpoints, has a countable dense subset, and is Dedekind complete. It is well known and easy to check that each of the three sum-orders above has these properties. See [4, 27] for more information.

When $J$ and the $I_j$ meet one of the conditions in proposition 7.1, the linear order $(I, <)$ is isomorphic to $(\mathbb{R}, <)$, and we will generally identify the two. Sometimes we will identify $(I, <)$ with an open interval of $\mathbb{R}$. It will always be stated explicitly when these identifications are made.

### 7.2 Functions on linear orders

We continue to let $(J, <)$ be a linear order, $I_j$ ($j \in J$) an interval of $\mathbb{R}$, and $I = \sum_{j \in J} I_j$. Let $W$ be a non-empty set, and for each $j \in J$ let $f_j : I_j \to W$ be a map.

We define a map

$$f = \sum_{j \in J} f_j : I \to W$$

by

$$f(\langle i, j \rangle) = f_j(i).$$

In the case where $(J, <) = (\{0, 1, \ldots, n\}, <)$, we may write the sum explicitly as $f_0 + \cdots + f_n$. If $I_j$ is a singleton $\{x\}$ and $f_j(x) = s$, say, we may write the map $f_j$ simply as $s$.

This ‘sum’ notation for functions should not be confused with (for example) the pointwise sum of real-valued functions, and in fact, in our applications the set $W$ will be the set of worlds of a Kripke frame and will have no ‘+’ operation defined on it.

**Example 7.2.** If $w_0, \ldots, w_n \in W$ then, modulo a renaming of the elements of its domain, $w_0 + \cdots + w_n$ is the map $f : \{0, \ldots, n\} \to W$ given by $f(i) = w_i$ for each $i \leq n$. 

29
For $j \in J$ we define $\text{dom}_f(f_j) = I_j \times \{j\} \subseteq I$. We will sometimes regard $f_j$ as a map $f_j : \text{dom}_f(f_j) \rightarrow W$, via $(i,j) \mapsto f_j(i)$ for each $(i,j) \in \text{dom}_f(f_j)$. In effect, we identify $f_j$ with $f \restriction \text{dom}_f(f_j)$.

The notation $\text{dom}_f(f_j)$ is more convenient than the plain $I_j \times \{j\}$ for two reasons. First, in several places we will not have explicit notation for the $I_j$, and the notation saves us from the need to introduce any. Second, we will frequently be identifying $I$ with $\mathbb{R}$ via some tacit order isomorphism $\rho : I \rightarrow \mathbb{R}$, and we will carry over the notation $\text{dom}_f(f_j)$ via the identification. Formally, when this identification is in operation,

1. we will identify $f$ with the map $f \circ \rho^{-1} : \mathbb{R} \rightarrow W$,
2. we will redefine $\text{dom}_f(f_j)$ to denote the interval $\rho(I_j \times \{j\})$ of $\mathbb{R}$,
3. we will sometimes identify $f_j$ with the map $f \circ \rho^{-1} \upharpoonright \rho(I_j \times \{j\})$ defined on this interval.

### 7.3 Shuffles

There is an important special case known as the shuffle. Reynolds [26] described a shuffle as a ‘thorough mixture’ of its ingredients. Keeping $W$ as above, let $\mathcal{G}$ be a countable (possibly empty) set of maps of the form $g : K_g \rightarrow W$, where $K_g$ is an interval of $\mathbb{R}$ with a least and a greatest element. Suppose also that $g_0 : K_{g_0} \rightarrow W$ is a map, where $K_{g_0}$ is a singleton interval of $\mathbb{R}$. Choose any $\theta : \mathbb{R} \rightarrow \mathcal{G} \cup \{g_0\}$ such that $\theta(j) = g_0$ for every irrational $j$, and $\theta^{-1}(g)$ is a dense subset of $\mathbb{Q}$ for each $g \in \mathcal{G}$. This is not difficult to do. Then $\theta^{-1}(g)$ is dense in $\mathbb{R}$ for every $g \in \mathcal{G} \cup \{g_0\}$. Now define $I_j = K_{\theta(j)}$ for each $j \in \mathbb{R}$, so that $\theta(j) : I_j \rightarrow W$, and let

$$I = \sum_{j \in \mathbb{R}} I_j, \quad \sigma = \sum_{j \in \mathbb{R}} \theta(j) : I \rightarrow W.$$

Then $\sigma((i,j)) = (\theta(j))(i) \in W$.

An element $x \in I$ is said to be a $\sigma$-endpoint if it is of the form $(i,j)$, where $j \in \mathbb{R}$ and $i$ is the least or greatest element of $I_j$.

**Lemma 7.3.** Let $I, \sigma$ be as above, let $x, y, z \in I$ with $y < x < z$, and suppose that $x$ is a $\sigma$-endpoint. Then $\sigma((y,z)) = \text{rng}(\sigma)$.

**Proof.** We show that $\text{rng} \sigma \subseteq \sigma((y,z))$ (the converse inclusion is trivial). Fix arbitrary $s \in \text{rng} \sigma$. Pick $g \in \mathcal{G} \cup \{g_0\}$ and $k \in K_g$ with $g(k) = s$. Suppose $x = (i,j)$, say, and suppose that $i$ is the least element of $I_j$ (the case where it is the greatest element of $I_j$ is similar). If $y = (i', j')$, say, then we must have $j' < j$. Now $\theta^{-1}(g)$ is dense in $\mathbb{R}$, so we may pick $j^* \in \theta^{-1}(g)$ with $j' < j^* < j$. Then $y < (k, j^*) < z$ and $s = \sigma((k, j^*)) \in \sigma((y,z))$ as required.

**Corollary 7.4.** Let $I, \sigma$ be as above. Then $\sigma^{-1}(s)$ is unbounded in $I$ for each $s \in \text{rng}(\sigma)$.

**Proof.** This follows from the lemma, as the set of $\sigma$-endpoints is unbounded in $I$.  

30
By proposition 7.1(3), the linear order \((I, <)\) is isomorphic to \((\mathbb{R}, <)\), so by choosing a suitable isomorphism we can regard \(\sigma\) as a map \(\sigma : \mathbb{R} \to W\). This map depends on the choices of the isomorphism and \(\theta\), but any choices will do for us and in fact all choices lead to the same result modulo an automorphism (order-preserving permutation) of \((\mathbb{R}, <)\). So we let

\[
\text{Shuffle}(G ; g_0)
\]
denote a map \(\sigma : \mathbb{R} \to W\) as above, for arbitrary tacit choices of these items. The elements of \(G \cup \{g_0\}\) are called the ingredients of the shuffle.

**EXAMPLE 7.5.** If \(a, b, c \in W\) then \(\text{Shuffle}\{a, b\}; c\) can be taken to be a map \(\sigma : \mathbb{R} \to \{a, b, c\}\) such that \(\sigma^{-1}(a), \sigma^{-1}(b)\) are dense sets of rationals and \(\sigma^{-1}(c) = \mathbb{R} \setminus \mathbb{Q}\).

### 7.4 S4 frames

We now use lexicographic sums to establish a relative of the McKinsey–Tarski theorem that the logic of \(\mathbb{R}\) in the language with \(\Box\) is S4 \([20]\). It will be needed in \(\S 7.5\).

A similar method is used in \([10]\) to prove the McKinsey–Tarski theorem itself, and others. There is also very substantial similarity to the methods used in \([20, 24]\).

**DEFINITION 7.6.** An S4-frame is a pair \((W, R)\), where \(R\) is a reflexive and transitive binary relation on the non-empty set \(W\).

**DEFINITION 7.7.** Let \(F = (W, R)\) be an S4-frame, \((I, <)\) a linear order, and \(g : I \to W\) a map. We say that an element \(x \in I\) is \(g\)-fair (with respect to \(F\)) if there are \(y, z \in I\) with \(y < x < z\) and such that \(g((y', z')) = R(g(x))\) for every \(y', z' \in I\) with \(y \leq y' < x < z' \leq z\).

To motivate the definition, consider a Kripke model \(M = (W, R, h)\) and a map \(g : \mathbb{R} \to W\). Let \(h' : PV \to \wp(\mathbb{R})\) be the assignment induced from \(M\) by \(g\), via \(h'(p) = g^{-1}(h(p))\) for \(p \in PV\). The reader is invited to check that if every \(x \in \mathbb{R}\) is \(g\)-fair then \(g\) preserves all modal formulas: \((\mathbb{R}, h'), x \models \varphi\) iff \(M, g(x) \models \varphi\) for every \(x \in \mathbb{R}\) and every \(L\)-formula \(\varphi\) not involving \(G\) or \(H\). See the claim in the proof of lemma 7.25 below.

**REMARK 7.8.** Clearly, if \(F\) is an \(R\)-generated subframe of an S4-frame \(G\), a point \(x \in I\) is \(g\)-fair with respect to \(F\) iff it is \(g\)-fair with respect to \(G\).

Where the meaning is clear from the context, we will usually say simply that \(x\) is \(g\)-fair.

**REMARK 7.9.** Fairness is clearly a ‘local’ property depending only on arbitrarily small neighbourhoods of the point in question. So if \(g = \sum_{j \in J} f_j\), \(j \in J\), and \(x \in \text{dom}_g(f_j)\) is in the interior of \(\text{dom}_g(f_j)\) (that is, \(x\) is not a least or greatest element of \(\text{dom}_g(f_j)\)), then \(x\) is \(g\)-fair iff it is \(f_j\)-fair. (Recall here that we identify \(f_j\) with \(g \upharpoonright \text{dom}_g(f_j)\).)

**THEOREM 7.10.** Let \(F = (W, R)\) be a finite connected S4-frame (connected frames were defined in definition 5.2). Then there is a map \(g : \mathbb{R} \to W\) satisfying:
1. every \( x \in \mathbb{R} \) is \( g \)-fair (with respect to \( \mathcal{F} \)),

2. \( g^{-1}(w) \) is unbounded in \( \mathbb{R} \) for every \( w \in \mathcal{W} \).

**Proof.** Recall from definition 2.1 that \( R^*wu \) means that \( Rwu \land \neg Rwz \). As \( \mathcal{F} \) is finite, we can define for each \( w \in \mathcal{W} \) a map \( \nu_w : \mathbb{R} \to \mathcal{W} \) by complete induction on \( |R(w)| \):

\[
\nu_w = \text{Shuffle}\{\{w + \nu_u + w : u \in R^*(w)\} \cup \{u : Rwu \land Rwz\} ; w\}.
\]

This is well defined because (a) for each \( u \in R^*(w) \), since \( R \) is transitive we have \( R(u) \subseteq R(w) \), and plainly \( w \in R(w) \setminus R(u) \), so \( |R(u)| < |R(w)| \) and hence \( \nu_u \) is defined inductively, (b) the domain of each map \( w + \nu_u + w \) and of each map \( u \) can be taken to be an interval of \( \mathbb{R} \) with a least and a greatest point (for \( u \) it is a singleton interval), and (c) the domain of the map \( w \) is some singleton interval of \( \mathbb{R} \).

**Claim.** For each \( w \in \mathcal{W} \):

1. \( \text{rng}(\nu_w) = R(w) \).
2. Every \( x \in \mathbb{R} \) is \( \nu_w \)-fair.

**Proof of claim.** The proof is by complete induction on \( |R(w)| \). Inductively assume the claim for all \( u \in R^*(w) \). For part 1, \( \text{rng}(\nu_w) \) is clearly the union of the ranges of the ingredients of the shuffle defining \( \nu_w \). For any \( u \in \mathcal{W} \), the range of the map \( u \) is just \( \{u\} \). So using the inductive hypothesis,

\[
\text{rng}(\nu_w) = \big( \bigcup_{u \in R^*(w)} \{\{w\} \cup \text{rng}(\nu_u) \cup \{w\}\} \big) \cup \{u : Rwu \land Rwz\} \cup \{w\} \\
= \big( \bigcup_{u \in R^*(w)} \text{rng}(u) \big) \cup \{u : Rwu \land Rwz\} \cup \{w\} \\
= R(w).
\]

This proves part 1. For part 2, take \( x \in \mathbb{R} \). We show that \( x \) is \( \nu_w \)-fair. If \( x \) is a \( \nu_w \)-endpoint (see §7.3), suppose that \( \nu_w(x) = u \), say. The definition of \( \nu_w \) tells us that either \( u = w \), or \( Rwu \) and \( Rwz \). In both cases, by transitivity of \( R \) we have \( R(u) = R(w) \). By lemma 7.3 and part 1, whenever \( y < x < z \) we have

\[
\nu_w((y, z)) = \text{rng}(\nu_w) = R(w) = R(u).
\]

It follows that \( x \) is \( \nu_w \)-fair. If \( x \) is not a \( \nu_w \)-endpoint, then \( x \) is in the interior of the domain of \( \nu_u \) for some \( u \in R^*(w) \). Inductively, \( x \) is \( \nu_u \)-fair, and hence (see remark 7.9) it is \( \nu_w \)-fair as well. This proves the claim.

Now \( \mathcal{F} \) is connected and \( R \) is reflexive and transitive. It follows that \( \mathcal{F} \) is path-connected in the sense that for each \( u, v \in \mathcal{W} \) there are \( w_0, \ldots, w_n \in \mathcal{W} \) (for some finite \( n \)) with \( w_0 = u, w_n = v, R(w_i, w_{i+1}) \) for each even \( i < n \), and \( R(w_{i+1}, w_i) \) for each odd \( i < n \). Using this and the finiteness of \( \mathcal{F} \), it is straightforward to find an infinite zigzag path through \( \mathcal{F} \) that visits each point infinitely often. Formally, there are \( a_i, b_i \in \mathcal{W} \) (\( i \in \mathbb{Z} \)) satisfying:

- \( Ra_i b_{i-1} \) and \( Ra_i b_i \) for each \( i \in \mathbb{Z} \),
- for each \( w \in \mathcal{W} \), the set \( \{i \in \mathbb{Z} : a_i = w\} \) is unbounded in \( \mathbb{Z} \).
We would like to define \( g = \sum_{i \in \mathbb{Z}} (a_i + \nu_{a_i} + a_i + \nu_{b_i}) \), but the notation may be easier to follow if we avoid nested sums. So for each \( i \in \mathbb{Z} \), define functions as follows:

\[
\begin{align*}
  f_{4i} &= f_{4i+2} = a_i, \\
  f_{4i+1} &= \nu_{a_i}, \\
  f_{4i+3} &= \nu_{b_i}.
\end{align*}
\]

We now define our desired map \( g : \mathbb{R} \to W \) by

\[
g = \sum_{j \in \mathbb{Z}} f_j.
\]

By proposition 7.1(2), \( \text{dom}(g) \) is order-isomorphic to \( \mathbb{R} \). As usual, we identify the two, and identify each restriction \( g \upharpoonright \text{dom}_g(f_j) \) of \( g \) with \( f_j \).

Let \( x \in \mathbb{R} \) be arbitrary. We show that it is \( g \)-fair. Fix the unique \( j \in \mathbb{Z} \) such that \( x \in \text{dom}_g(f_j) \). There are four cases. If \( j = 4i + 1 \) for some \( i \in \mathbb{Z} \), then \( f_j = \nu_{a_i} \). By the claim, \( x \) is \( \nu_{a_i} \)-fair, and hence (remark 7.9) it is \( g \)-fair. The case where \( j = 4i + 3 \) for some \( i \in \mathbb{Z} \) is similar.

Suppose \( j = 4i + 2 \) for some \( i \in \mathbb{Z} \). So \( f_j \) is the map \( a_i \), \( g(x) = a_i \), and the maps \( f_{j-1} = \nu_{a_i} \) and \( f_{j+1} = \nu_{b_i} \) are shuffles. Take any \( y \in \text{dom}_g(f_{j-1}) \) and \( z \in \text{dom}_g(f_{j+1}) \), so that \( y < x < z \). By applying corollary 7.4 and part 1 of the claim to \( \nu_{a_i} \) and \( \nu_{b_i} \), we see that

\[
\begin{align*}
  g((y, x)) &= \text{rng}(\nu_{a_i}) = R(a_i), \\
  g((x, z)) &= \text{rng}(\nu_{b_i}) = R(b_i).
\end{align*}
\]

Consequently, \( g((y, z)) = g((y, x)) \cup \{g(x)\} \cup g((x, z)) = R(a_i) \cup \{a_i\} \cup R(b_i) \). But \( a_i \in R(a_i) \), and moreover, since \( Ra_i b_i \), transitivity yields \( R(b_i) \subseteq R(a_i) \). So this union is just \( R(a_i) \) — i.e., \( R(g(x)) \). Thus, \( g((y, z)) = R(g(x)) \) for every \( y \in \text{dom}_g(f_{j-1}) \) and \( z \in \text{dom}_g(f_{j+1}) \). Since all sufficiently large \( y < x \) lie in \( \text{dom}_g(f_{j-1}) \) and all sufficiently small \( z > x \) lie in \( \text{dom}_g(f_{j+1}) \), it follows that \( x \) is \( g \)-fair as required.

A similar argument covers the case where \( j = 4i \) for some \( i \in \mathbb{Z} \). We simply note that the left and right neighbours of \( x \) are then \( \nu_{b_i-1} \) and \( \nu_{a_i} \), respectively, and that \( Ra_i b_{i-1} \). So in all cases, \( x \) is \( g \)-fair. This proves part 1 of the theorem.

For part 2, let \( w \in W \) and \( r \in \mathbb{R} \) be given. The set \( \{i \in \mathbb{Z} : a_i = w\} \) is unbounded in \( \mathbb{Z} \), so we can take \( i, j \in \mathbb{Z} \) such that \( a_i = w \), \( j = 4i \) (so \( f_j = a_i \)), and so large that \( r < x \) for the unique \( x \in \text{dom}_g(f_j) \). Then \( g(x) = a_i = w \). So \( g^{-1}(w) \) has no upper bound, and a symmetrical argument shows that it has no lower bound either. \( \Box \)

### 7.5 Representing \( \Psi \)-linked models

Here, we prove the main result of this section:

**THEOREM 7.11.** Let \( \Psi \) be a finite set of \( \mathcal{L} \)-formulas closed under subformulas, let \( \varphi \in \Psi \), and suppose that \( \varphi \) is satisfied in some \( \Psi \)-linked Kripke model. Then \( \varphi \) is satisfiable over \( \mathbb{R} \).

To prove it, fix \( \varphi, \Psi \) as in the statement of the theorem, and let \( M = (W, \Box, R, h) \) be a \( \Psi \)-linked Kripke model in which \( \varphi \) is satisfied. We will use theorem 7.10 to
define (in definition 7.18) a map \( g : \mathbb{R} \to W \) that will induce a model over \( \mathbb{R} \), and we will then prove that \( g \) preserves all formulas in \( \Psi \). The theorem will follow from this.

To define \( g \), we need to set out some terminology.

### 7.5.1 Clusters in the model

Since \( M \) is \( \Psi \)-linked (see definition 5.4), \( \preceq \) is prelinear and lemma 5.5 applies to the frame of \( M \). Thus we may enumerate, without repetitions, the \( \preceq \)-clusters in \( M \) as \( C_0, \ldots, C_k \) for some \( k \geq 0 \), with

\[
C_0 \preceq C_1 \preceq \cdots \preceq C_k.
\]

Let \( i < k \). Then \((C_i, C_{i+1})\) is a pair of consecutive \( \preceq \)-clusters. As \( M \) is \( \Psi \)-linked, there are two possibilities.

1. \( C_i \) and \( C_{i+1} \) are not adjacent, so there is \( u \in M \) with \( C_i \preceq u \preceq C_{i+1} \) and \( u \not\in C_i \cup C_{i+1} \). Then \( u \) is not in any \( \preceq \)-cluster, so is irreflexive. We must have \( C_i = \lambda(u) \) and \( C_{i+1} = \rho(u) \). It follows that \( u \) is unique. We define \( u_i \) to be this \( u \), and we say that \( i \) is open, \( C_i \) is right-open, and \( C_{i+1} \) is left-open.

2. \( C_i \) and \( C_{i+1} \) are adjacent, so as \( M \) is \( \Psi \)-linked, we can select \( d_i \in C_i \) and \( s_{i+1} \in C_{i+1} \) with \( d_i \equiv^M_{\Psi} s_{i+1} \). In this case, we say that \( i \) is closed, \( C_i \) is right-closed, and \( C_{i+1} \) is left-closed.

We also say that \( C_0 \) is left-open and \( C_k \) right-open. (We do not define \( k \) itself as either open or closed.)

### 7.5.2 The maps \( f_i \) and \( f_i' \)

The map \( g : \mathbb{R} \to W \) will be made from maps \( f_0, \ldots, f_k \) and \( f_0', \ldots, f_{k-1}' \). Up to an order automorphism of \( \mathbb{R} \), we will have \( g = \sum_{i<k} (f_i + f_i') + f_k \), but it may help the reader if we provide more specific notation for the domains of the components of this sum. So we choose elements

\[
-\infty = l_0 < r_0 \leq l_1 < r_1 \leq l_2 < r_2 \leq \cdots < r_{k-1} \leq l_k < r_k = \infty \quad (7.1)
\]

in \( \mathbb{R} \cup \{\pm \infty\} \), such that \( r_i = l_{i+1} \) iff \( i \) is open, for each \( i < k \). We will use these elements to define

- surjective maps \( f_i : (l_i, r_i) \to C_i \) for each \( i \leq k \),
- ‘filler’ maps \( f_i' : [r_i, l_{i+1}] \to W \) for each \( i < k \).

Unfortunately, the definitions involve a number of cases, because the \( C_i \) come in four kinds: left- or right-open, and left- or right-closed.

**Definition 7.12.** First we define the maps \( f_i \) for \( i \leq k \). Fix such an \( i \). We will actually define \( f_i \) by way of an auxiliary map, \( f_i^* \). First note that because \( M \) is \( \Psi \)-linked, \((C_i, R \upharpoonright C_i)\) is a finite connected \( \mathcal{S}4 \)-frame.
1. If $C_i$ is left-open and right-open then, observing that $(l_i, r_i)$ is order-isomorphic to $\mathbb{R}$, use theorem 7.10 to choose a map $f_i^*: (l_i, r_i) \to C_i$ satisfying the stated properties — to wit, every $x \in (l_i, r_i)$ is $f_i^*$-fair with respect to $(C_i, R \upharpoonright C_i)$, and $(f_i^*)^{-1}(w)$ is unbounded in $(l_i, r_i)$ for every $w \in C_i$.

2. If $C_i$ is left-open and right-closed, first use theorem 7.10 to choose a map $f_i^*: (l_i, \infty) \to C_i$ satisfying the stated properties. The properties ensure that there is $x > l_i$ with $f_i^*(x) = d_i$. By some scaling, we can suppose that $x = r_i$.

3. If $C_i$ is left-closed and right-open, we use a mirror image argument to choose a map $f_i^*: (-\infty, r_i) \to C_i$ with $f_i^*(l_i) = s_i$.

4. If $C_i$ is left-closed and right-closed, we combine the preceding two cases, with a little extra work to ensure surjectivity. Using theorem 7.10, choose a map $f_i^*: \mathbb{R} \to C_i$ with the stated properties. By the properties and the finiteness of $C_i$, there are $x < y$ in $\mathbb{R}$ with $f_i^*(x) = s_i$, $f_i^*(y) = d_i$, and $f_i^*((x, y)) = C_i$. By scaling, we can assume that $x = l_i$ and $y = r_i$.

We now define $f_i = f_i^* \upharpoonright (l_i, r_i)$.

**Lemma 7.13.** Let $i \leq k$ and $x \in (l_i, r_i)$. If $C_i$ is left-open then $f_i((l_i, x)) = C_i$. If $C_i$ is right-open then $f_i((x, r_i)) = C_i$.

**Proof.** Suppose that $C_i$ is left-open. Certainly, $f_i((l_i, x)) \subseteq \text{rng}(f_i^*) = C_i$. To prove the converse inclusion, let $w \in C_i$ be given. Because $C_i$ is left-open, $\text{dom}(f_i^*)$ has the form $(l_i, z)$ where either $z = r_i$ or $z = \infty$ (see definition 7.12(1,2)). By theorem 7.10, $(f_i^*)^{-1}(w)$ is unbounded in $\text{dom}(f_i^*)$, so there is $y \in (l_i, x)$ with $f_i^*(y) = w$. By definition, $f_i = f_i^* \upharpoonright (l_i, r_i)$, so $f_i(y) = w$ and hence $w \in f_i((l_i, x))$. Since $w$ was arbitrary, $C_i \subseteq f_i((l_i, x))$, proving the first part. The second part is a mirror image. □

**Corollary 7.14.** For each $i \leq k$, the map $f_i: (l_i, r_i) \to C_i$ is surjective.

**Proof.** This is immediate from lemma 7.13 except when $C_i$ is left-closed and right-closed (case 4 of definition 7.12). But in that case, we arranged explicitly that $f_i((l_i, r_i)) = C_i$. □

**Lemma 7.15.** Suppose that $i < k$ is closed. Then $f_i(((y, r_i)) \subseteq R(d_i)$ for some $y \in (l_i, r_i)$, and $f_{i+1}((l_{i+1}, z)) \subseteq R(s_{i+1})$ for some $z \in (l_{i+1}, r_{i+1})$.

**Proof.** Here, $C_i$ is right-closed, $C_{i+1}$ is left-closed, and $d_i, s_{i+1}$ are defined. By theorem 7.10, $r_i$ is $f_i^*$-fair, so there are $y, z \in \text{dom}(f_i^*)$ with $l_i < y < r_i < z$ and $f_i^*((y, z)) = R(f_i^*(r_i)) = R(d_i)$. Then $f_i((y, r_i)) = f_i^*((y, r_i)) \subseteq f_i^*((y, z)) = R(d_i)$. This proves the first part of the lemma, and the second part is a mirror image. □

**Definition 7.16.** Next we define the maps $f_i': [r_i, l_{i+1}] \to W$ for each $i < k$.

1. If $i$ is open, then $r_i = l_{i+1}$ and $u_i$ is defined. Define $f_i'$ simply by $f_i'(r_i) = u_i$. 

35

2. If \( i \) is closed, then \( C_i \) is right-closed, \( C_{i+1} \) is left-closed, and \( d_i, s_i + 1 \) are defined. Plainly, \((R(d_i), R \upharpoonright R(d_i))\) is a finite S4-frame. It is trivially connected, because if \( R(d_i) \) is the union of disjoint \( R \)-generated subsets \( X, Y \), then supposing without loss of generality that \( d_i \in X \), we have \( R(d_i) \subseteq X \) and so \( Y = \emptyset \). Noting that \((r_i, l_{i+1})\) is order-isomorphic to \( \mathbb{R} \) in this case, we may therefore choose a map \( f'_i : (r_i, l_{i+1}) \rightarrow R(d_i) \) satisfying the conditions of theorem 7.10— to wit, each \( x \in (r_i, l_{i+1}) \) is \( f'_i \)-fair with respect to \((R(d_i), R \upharpoonright R(d_i))\), and \( f_i'^{-1}(w) \) is unbounded in \((r_i, l_{i+1})\) for each \( w \in R(d_i) \). We extend \( f_i' \) to the whole of \([r_i, l_{i+1}]\) by defining \( f_i(r_i) = d_i \) and \( f_i'(l_{i+1}) = s_{i+1} \). (So in this case, \( f_i'([r_i, l_{i+1}]) \subseteq C_i \) but \( f_i'(l_{i+1}) \in C_{i+1} \).)

**Lemma 7.17.** Suppose that \( i < k \) is closed and let \( x \in (r_i, l_{i+1}) \). Then \( f_i'((r_i, x)) = f_i'((x, l_{i+1})) = R(d_i) \).

**Proof.** As in lemma 7.13, theorem 7.10’s conditions imply that \((r_i, l_{i+1}) \cap f_i'^{-1}(w)\) is unbounded in \((r_i, l_{i+1})\) for each \( w \in R(d_i) \), from which the lemma follows. \( \square \)

### 7.5.3 The map \( g \)

**Definition 7.18.** We finally define \( g = (\bigcup_{i < k} f_i) \cup (\bigcup_{i < k} f_i') : \mathbb{R} \rightarrow W \). That is, for each \( x \in \mathbb{R} \),

\[
g(x) = \begin{cases} 
  f_i(x), & \text{if } x \in (l_i, r_i) \text{ for some } i \leq k, \\
  f_i'(x), & \text{if } x \in [r_i, l_{i+1}] \text{ for some } i < k.
\end{cases}
\]

This is plainly well defined.

**Example 7.19.** An example of the construction of \( g \) is shown in figure 2. In the figure, \( C_0 \) and \( C_4 \) are left- and right-open, \( C_1 \) is left-open and right-closed, \( C_2 \) is left- and right-closed, and \( C_3 \) is left-closed and right-open. The small circles inside \( C_1 \) and \( C_2 \) are \( d_1 \) and \( s_2 \), respectively, and the big circles are \( R(d_1) \) and \( R(s_2) \), respectively. Similarly, the element \( d_2 \) is the small square inside \( C_2 \), and the large square is \( R(d_2) \).

The large square inside \( C_3 \) is \( R(s_3) \) and \( s_3 \) is the small square inside it. We can see that \( R(d_1) \) is used in a sense as intervening material for \( g \) between \( C_1 \) and \( C_2 \) via \( f'_1 \).
and similarly with $R(d_2)$. For an example of how the construction produces a model of $\varphi$ over $\mathbb{R}$, see §7.6.

### 7.5.4 Properties of $g$

We establish a few properties of $g$, useful below.

**LEMMA 7.20.** For each $i \leq k$,

$$Y_i = \{x \in \mathbb{R} : g(x) \sqsubseteq C_i\} = \begin{cases} (-\infty, l_{i+1}), & \text{if } i < k, \\ \mathbb{R}, & \text{if } i = k. \end{cases}$$

**Proof.** If $i = k$, the result is trivial since $W \sqsubseteq C_k$. Let $i < k$. If $x < l_{i+1}$, then $g(x)$ is $f_j(x)$ or $f'_j(x)$ for some $j \leq i$, so by inspection, $g(x) \in C_j$ for some $j \leq i$, or $g(x) = u_j$ for some $j < i$ (we have $j \neq i$ since $x \neq l_{i+1}$). It follows that $g(x) \sqsubseteq C_i$. If $x \geq l_{i+1}$ then $g(x) = u_j$ for some $j \geq i$ or $g(x) \in C_j$ for some $j > i$, so $-g(x) \sqsubseteq C_i$. \(\square\)

**LEMMA 7.21.** The map $g : \mathbb{R} \to W$ is surjective and order preserving: if $x < y$ in $\mathbb{R}$ then $g(x) \sqsubseteq g(y)$.

**Proof.** Surjectivity is immediate from corollary 7.14 and the fact that $g(r_i) = u_i$ for every $i < k$ such that $u_i$ is defined. We check that $g$ is order preserving. Assume $x < y$. Suppose first that $g(y) \in C_i$ for some $i \leq k$. Then $y \in Y_i$. By lemma 7.20, $Y_i$ is closed downwards under $<$, so $x \in Y_i$ as well. Hence $g(y) \in C_i \sqsubseteq g(x)$ as required. If on the other hand $g(y) = u_i$ for some $i < k$, then the definition of $g$ yields $y = l_{i+1} > x$, so $x \in Y_i$ by lemma 7.20. Hence $g(x) \sqsubseteq C_i \sqsubseteq u_i = g(y)$ as required. \(\square\)

**LEMMA 7.22.** Each $x \in \mathbb{R} \setminus \{r_i, l_{i+1} : i < k\}$ is $g$-fair with respect to the frame of $\mathcal{M}$.

**Proof.** Each such $x$ is in the interior of $\text{dom}(f_i)$ for some $i \leq k$ or the interior of $\text{dom}(f'_i)$ for some $i < k$. As $f_i$ and $f'_i$ were defined using theorem 7.10, in the former case $x$ is $f_i$-fair with respect to $(C_i, R \restriction C_i)$, and in the latter case $x$ is $f'_i$-fair with respect to $(R(d_i), R \restriction R(d_i))$. These are $R$-generated subframes of the frame of $\mathcal{M}$. By remarks 7.8 and 7.9, $x$ is $g$-fair with respect to the frame of $\mathcal{M}$. \(\square\)

**LEMMA 7.23.** Let $i \leq k$ and $x \in (l_i, r_i)$.

1. If $C_i$ is left-open then $g((l_i, x)) = C_i$.
2. If $C_i$ is right-open then $g((x, r_i)) = C_i$.

**Proof.** Immediate from lemma 7.13, since $g \restriction (l_i, r_i) = f_i$. \(\square\)

**LEMMA 7.24.** Suppose that $i < k$ is closed.

1. $g(y, r_i) \subseteq R(d_i)$ for some $y < r_i$.
2. $g((r_i, x)) = g((x, l_{i+1})) = R(d_i)$ for every $x \in (r_i, l_{i+1})$.
3. $g((l_{i+1}, z)) \subseteq R(s_{i+1})$ for some $z > l_{i+1}$.

**Proof.** Since $g \restriction (l_i, r_i) = f_i$ and $g \restriction (l_{i+1}, r_{i+1}) = f_{i+1}$, parts 1 and 3 follow from lemma 7.15. Part 2 follows from lemma 7.17, since $g \restriction (r_i, l_{i+1}) = f'_i$. \(\square\)
7.5.5 The model \( \mathcal{R} \)

We define an assignment \( h' \) into \( \mathbb{R} \) by \( h'(p) = g^{-1}(h(p)) \), for each atom \( p \). We let \( \mathcal{R} = (\mathbb{R}, h') \). This is our intended model. We now prove a ‘truth lemma’ for it, from which theorem 7.11 will easily follow.

**Lemma 7.25.** For every \( \psi \in \Psi \) and \( x \in \mathbb{R} \) we have \( \mathcal{R}, x \models \psi \) iff \( \mathcal{M}, g(x) \models \psi \).

**Proof.** By induction on \( \psi \). The lemma for atomic \( \psi \) is immediate from the definition of \( h' \), and the boolean cases are easy. The main cases are \( G\psi \), \( H\psi \), and \( \Box \psi \). Since \( \Psi \) is closed under subformulas, \( \psi \in \Psi \) as well, so inductively assume the lemma for \( \psi \):

\[
\mathcal{R}, x \models \psi \iff \mathcal{M}, g(x) \models \psi \quad \text{for every} \ x \in \mathbb{R} \quad (\text{inductive hypothesis}) \quad (7.2)
\]

First we deal with the temporal operators. If \( \mathcal{M}, g(x) \models G\psi \) then take arbitrary \( y \in \mathbb{R} \) with \( y > x \). By lemma 7.21, \( g \) is order preserving, so \( g(x) \sqsubseteq g(y) \) and hence \( \mathcal{M}, g(y) \models \psi \). Inductively, \( \mathcal{R}, y \models \psi \), and as \( y \) was arbitrary, \( \mathcal{R}, x \models G\psi \).

Conversely, suppose that \( \mathcal{M}, g(x) \models \neg G\psi \). As \( W \) is finite and \( \sqsubseteq \) transitive and prelinear, we may choose \( w \in W \) such that \( \mathcal{M}, w \models \neg \psi \) and \( w \sqsubseteq u \) for all \( u \in W \) with \( \mathcal{M}, u \models \neg \psi \). Such a \( w \) is a ‘\( \sqsubseteq \) maximal’ witness to \( \neg \psi \) in \( \mathcal{M} \). It should be plain that \( g(x) \sqsubseteq w \). We show that

\[
\text{there is } y > x \text{ in } \mathbb{R} \text{ with } g(y) = w. \quad (7.3)
\]

To prove (7.3), there are two cases.

**Case 1:** \( w = u_i \) for some \( i < k \). We have \( g(x) \sqsubseteq w = u_i \), so \( g(x) \sqsubseteq \lambda(u_i) = C_i \).

By lemma 7.20, \( x \in Y_i = (-\infty, l_{i+1}) \). So \( x < l_{i+1} \), and by definition of \( g \),

\[
g(l_{i+1}) = u_i = w, \quad \text{proving } (7.3) \text{ in this case.}
\]

**Case 2:** \( w \in C_i \) for some \( i \leq k \). We show first that \( C_i \) is right-open. Suppose for contradiction that \( C_i \) is right-closed. Then \( i < k \), the points \( d_i \) and \( s_{i+1} \) are defined, and \( w \) and \( d_i \) are in the same cluster, so \( d_i \sqsubseteq w \) and hence \( \mathcal{M}, d_i \models \neg G\psi \). But \( d_i \equiv_{\mathcal{B}^{\Psi}} s_{i+1} \) and \( G\psi \in \mathcal{B}^{\Psi} \), so \( \mathcal{M}, s_{i+1} \models \neg G\psi \) as well, and there is \( u \in W \) with \( s_{i+1} \sqsubseteq u \) and \( \mathcal{M}, u \models \neg \psi \). By choice of \( w \) we have \( u \sqsubseteq w \). So \( s_{i+1} \sqsubseteq u \sqsubseteq w \sqsubseteq d_i \). By transitivity, \( s_{i+1} \sqsubseteq d_i \). But this is a contradiction, because \( d_i \in C_i \), \( s_{i+1} \in C_{i+1} \), and \( C_{i+1} \) is a strictly \( \sqsubseteq \)-later cluster than \( C_i \). So \( C_i \) is indeed right-open.

Because \( C_i \) is right-open, if \( i < k \) then \( r_i = l_{i+1} \). Also, \( r_k = \infty \). So lemma 7.20 yields \( Y_i = \{ y \in \mathbb{R} : g(y) \sqsubseteq C_i \} = (-\infty, r_i) \). Since \( g(x) \sqsubseteq w \in C_i \), we have \( x \in Y_i \). As \( C_i \) is right-open, lemma 7.23(2) yields \( C_i \subseteq g((x, r_i)) \), so there is \( y > x \) with \( g(y) = w \), proving (7.3) in this case too.

So we may take \( y \) as in (7.3). Then \( \mathcal{R}, y \models \neg \psi \) by the inductive hypothesis (7.2), so \( \mathcal{R}, x \models \neg G\psi \) as required.

In spite of the temporal asymmetry of the definition of \( g \), the case of \( H\psi \) is so similar that we leave it to the reader.

Finally we consider \( \Box \psi \), the most interesting case. The following claim will make light of all but one of the subsequent subcases.

38
Claim. If \( x \) is \( g \)-fair then \( \mathcal{R}, x \models \Box \psi \) iff \( \mathcal{M}, g(x) \models \Box \psi \).

**Proof of claim.** Assume that \( x \) is \( g \)-fair. First suppose that \( \mathcal{M}, g(x) \models \Box \psi \). By \( g \)-fairness of \( x \), we can choose \( y, z \in \mathbb{R} \) with \( y < x < z \) and \( g((y, z)) \subseteq R(g(x)) \). Take arbitrary \( t \in (y, z) \). Then \( g(t) \in R(g(x)) \), so by Kripke semantics, \( \mathcal{M}, g(t) \models \psi \). By the inductive hypothesis (7.2), \( \mathcal{R}, t \models \psi \). As \( t \) was arbitrary, we obtain \( \mathcal{R}, x \models \Box \psi \).

Conversely, if \( \mathcal{R}, x \models \Box \psi \) then choose \( y < x < z \in \mathbb{R} \) such that \( \mathcal{R}, t \models \psi \) for all \( t \in (y, z) \). Pick arbitrary \( w \in R(g(x)) \). By \( g \)-fairness of \( x \) we have \( R(g(x)) \subseteq g((y, z)) \), so there is \( t \in (y, z) \) with \( g(t) = w \). Since \( t \in (y, z) \), we have \( \mathcal{R}, t \models \psi \), and inductively (see (7.2)), \( \mathcal{M}, w \models \psi \). Since \( w \) was arbitrary, \( \mathcal{M}, g(x) \models \Box \psi \). This proves the claim.

There are now four subcases.

1. If \( x \in \mathbb{R} \setminus \{r_i, l_{i+1} : i < k\} \) then by lemma 7.22, \( x \) is \( g \)-fair, and the claim gives \( \mathcal{R}, x \models \Box \psi \) iff \( \mathcal{M}, g(x) \models \Box \psi \) as required.
2. Suppose that \( x = l_{i+1} = r_i \) for some \( i < k \). We show that \( x \) is \( g \)-fair, and this is easy to do. As \( r_i = l_{i+1} \), we see that \( C_i \) is right-open, \( C_{i+1} \) is left-open, and \( g(x) = u_i \). Take any \( y, z \) with \( l_i < y < x < z < r_{i+1} \). Recalling that \( x = l_{i+1} = r_i \), by lemma 7.23 we have \( g((y, x)) = C_i \) and \( g((x, z)) = C_{i+1} \), so
   \[
   g((y, z)) = g((y, x)) \cup \{g(x)\} \cup g((x, z)) = C_i \cup \{u_i\} \cup C_{i+1} = R(u_i).
   \]
   Hence, \( x \) is \( g \)-fair. By the claim, \( \mathcal{R}, x \models \Box \psi \) iff \( \mathcal{M}, g(x) \models \Box \psi \).
3. Suppose that \( x = r_i < l_{i+1} \) for some \( i < k \). Then \( i \) is closed and \( g(x) = d_i \). By lemma 7.24(1), \( g((y, x)) \subseteq R(d_i) \) for all large enough \( y < x \). On the other side, if \( z \in (x, l_{i+1}) \) then by lemma 7.24(2), \( g((x, z)) = R(d_i) \). Consequently, for all large enough \( y \) and small enough \( z \) with \( y < x < z \), we have
   \[
   g((y, z)) = g((y, x)) \cup \{g(x)\} \cup g((x, z)) = g((y, x)) \cup \{d_i\} \cup R(d_i) = R(d_i).
   \]
   So once again, \( x \) is \( g \)-fair, and the claim yields \( \mathcal{R}, x \models \Box \psi \) iff \( \mathcal{M}, g(x) \models \Box \psi \).
4. Finally suppose that \( r_i < l_{i+1} = x \) for some \( i < k \). This case is the culmination of our work. The claim does not apply, as \( x \) is not \( g \)-fair: indeed, \( g((r_i, x)) \) is disjoint from \( R(g(x)) \).

Since \( r_i < l_{i+1} \), we know that \( C_i \) is right-closed, \( C_{i+1} \) is left-closed, \( d_i \) and \( s_{i+1} \) are both defined, \( g(x) = s_{i+1} \), and \( d_i \equiv^M_{\mathcal{B}_\Psi} s_{i+1} \).

Suppose on the one hand that \( \mathcal{R}, x \models \Box \psi \). We show first that \( \mathcal{M}, d_i \models \Box \psi \).

Choose \( y \in (r_i, x) \) with \( \mathcal{R}, t \models \psi \) for all \( t \in (y, x) \). Then \( g((y, x)) = R(d_i) \) by lemma 7.24(2). Let \( w \in R(d_i) \) be arbitrary. Choose \( t \in (y, x) \) with \( g(t) = w \).

Inductively (see (7.2)), \( \mathcal{M}, w \models \psi \). Since \( w \) was arbitrary, we obtain \( \mathcal{M}, d_i \models \Box \psi \) as required. But \( d_i \equiv^M_{\mathcal{B}_\Psi} s_{i+1} = g(x) \) and \( \Box \psi \in \mathcal{B}_\Psi \), so we have \( \mathcal{M}, g(x) \models \Box \psi \) as well.

Suppose on the other hand that \( \mathcal{M}, g(x) \models \Box \psi \). As \( g(x) = s_{i+1} \equiv^M_{\mathcal{B}_\Psi} d_i \) and \( \Box \psi \in \mathcal{B}_\Psi \), we have both \( \mathcal{M}, s_{i+1} \models \Box \psi \) and \( \mathcal{M}, d_i \models \Box \psi \). Hence, \( \mathcal{M}, w \models \psi \) for every \( w \in R(s_{i+1}) \cup R(d_i) \). Let \( y = r_i < x \). It follows from lemma 7.24(2)
that \( g((y, x)) = R(d_i) \). By lemma 7.24(3) there is \( z > x \) such that \( g((x, z)) \subseteq R(s_{i+1}) \). Of course, \( \{g(x)\} \subseteq R(s_{i+1}) \) too. So

\[
  g((y, z)) = g((y, x)) \cup \{g(x)\} \cup g((x, z)) \subseteq R(d_i) \cup R(s_{i+1}).
\]

Choose \( t \in (y, z) \) arbitrarily. By the above, \( g(t) \in R(d_i) \). So \( M, g(t) \models \psi \), and inductively (see (7.2)), \( R, t \models \psi \) as well. Since \( t \) was arbitrary, we obtain \( R, x \models \Box \psi \), as required.

This completes the induction and the proof.

Now choose \( w \in W \) with \( M, w \models \varphi \). By lemma 7.21, \( g \) is surjective, so there is \( x \in R \) with \( g(x) = w \). Since \( \varphi \in \Psi \), by the lemma we obtain \( R, x \models \varphi \). Thus, \( \varphi \) is satisfiable over \( R \), proving theorem 7.11.

7.6 Example

We give a brief example of the construction of \( R \). Recall from proposition 5.6 that the formula

\[
\theta = H\neg a \land H\neg b \land \neg a \land \neg b \land \Diamond a \land \Diamond b \land G\neg(\Diamond a \land \Diamond b) \land FG\neg a
\]

of (4.2) is true at world \( u_0 \) in the \( \Psi \)-linked Kripke model \( M \) shown in figure 3, where \( \Psi \) is the set of subformulas of \( \theta \).

![Figure 3: Kripke model \( M \) satisfying \( \theta \)](image)

Following the route taken in §7.5, we select points \(-\infty = l_0 < r_0 = l_1 < r_1 < l_2 < r_2 = l_3 < r_3 = \infty \) in \( \mathbb{R} \) \( \cup \{\pm \infty\} \). Theorem 7.10 yields maps \( f_i^* : \mathbb{R} \to C_i \) for \( i = 0, 1, 2, 3 \), which we scale and chop to give maps \( f_i : (l_i, r_i) \to C_i \). For \( i \neq 1 \) there is no choice for \( f_i \), since \( |C_i| = 1 \). For \( f_1^* : \mathbb{R} \to C_1 \), the sequence \( a_i, b_i \) \((i \in \mathbb{Z})\) in the proof of theorem 7.10 looks like

\[
\cdots a_{-2} b_{-2} a_{-1} b_{-1} a_0 b_0 a_1 b_1 a_2 b_2 a_3 b_3 a_4 b_4 a_5 b_5 \cdots
\]

\[
\cdots a d_1 d_1 d_1 b d_1 d_1 d_1 a d_1 d_1 d_1 b d_1 d_1 d_1 \cdots
\]

so \( f_1^* \) is a \( \mathbb{Z} \)-sum of maps taking singletons to \( a, b, d_1 \) and open intervals of \( \mathbb{R} \) to \( d_1 \). Up to isomorphism, it maps odd integers to the point satisfying \( a \) in \( C_1 \), even integers to the point satisfying \( b \), and non-integers to \( d_1 \). We choose a non-integer, say \(-0.5,\)
and scale \( f_1^* \upharpoonright (-\infty, -0.5) \) to \((l_1, r_1)\), yielding our map \( f_1 : (l_1, r_1) \rightarrow C_1 \). The odd negative integers, when scaled, form a sequence of points in \((l_1, r_1)\) converging to \( l_1 \) and mapping to \( a \) under \( f_1 \), and there is a similar sequence for \( b \) arising from the even negative integers. There is no choice over the maps \( f'_i \), since by the definitions we have 
\[
\begin{align*}
f'_0 : [r_0, l_1] & \rightarrow \{u_0\}, \quad f'_1 : [r_1, l_2] \rightarrow R(d_1) = \{d_1\}, \quad f'_1(l_2) = s_2, \quad \text{and} \quad f'_2 : [r_2, l_3] \rightarrow \{u_2\}.
\end{align*}
\]

Figure 4 sketches these maps. We let \( g : \mathbb{R} \rightarrow M \) be the union of all of them. The model over \( \mathbb{R} \) induced by \( g \) is shown in figure 5. It should be clear that \( \theta \) is true at \( l_1 \).

![Figure 4](image_url)

Figure 4: the maps \( f_i \) and \( f'_i \) (\( i = 0, 1, 2 \) and \( f_3 \))

![Figure 5](image_url)

Figure 5: the map \( g : \mathbb{R} \rightarrow M \)

8 Conclusion

We can now prove our main result:

**Theorem 8.1.** The system of \( \S 3.1 \) axiomatises the \( \mathcal{L} \)-logic of \( \mathbb{R} \).

*Proof.* Soundness was shown in theorem 3.1. Conversely, let \( \varphi_0 \) be a formula consistent with the system of \( \S 3.1 \). Let \( \Psi \) be the set of subformulas of \( P \varphi_0 \). By theorem 6.1, \( \varphi_0 \) is satisfied in a \( \Psi \)-linked Kripke model. By theorem 7.11, \( \varphi_0 \) is satisfiable over \( \mathbb{R} \). Hence, any consistent formula is satisfiable over \( \mathbb{R} \). \( \square \)

We have shown that the logic of \( \mathbb{R} \) in the temporal language \( \mathcal{L} \) with modalities \( G, H, \) and \( \Box \)
• is finitely axiomatisable, answering an implicit problem of Shehtman [28],
• has PSPACE-complete complexity,
• has no strongly complete axiomatisation,
• is not Kripke complete.

We list some remaining open problems. First, some complexity problems.

**PROBLEM 8.2.** For fixed $k \geq 0$, what is the complexity of the set of $L$-formulas that are satisfiable over $\mathbb{R}$ and involve at most $k$ $\Box$-operators?

The methods of [23] may be helpful. If the answer is ‘NP-complete’, it might suggest that the language with $F$, $P$, and $\Box$ could be more tractable in practice than the more expressive language with Until and Since.

The operations of sum (+) and shuffle in §7, plus two more involving countable iterations, can be used to specify models over $\mathbb{R}$ in a finite way. By results in [4], any model over $\mathbb{R}$ can be specified up to any desired degree of first-order equivalence in such a way, so any satisfiable $L$-formula has a model specified by these operations. This leads to the following problem.

**PROBLEM 8.3.** Investigate the complexity of model checking for the language $L$ for models over $\mathbb{R}$ specified by a finite sequence of operations of the above kinds.

This problem was investigated in [6] for the language with Until and Since. It was shown to be in PSPACE in [19] and PSPACE-complete in [8]. One may also wish to develop alternative reasoning systems for $L$ over $\mathbb{R}$, such as tableaux, and synthesis methods along the lines of [6, 7]. The end result of this research could justify the promotion of $L$ as a viable language for specification and reasoning over the real line, possibly a more attractive one than the very expressive language with Until and Since.

It may be of interest to study the logic of $\mathbb{R}$ in the sublanguage of $L$ without $H$: the only non-boolean connectives are $G$ and $\Box$. This logic is PSPACE-complete, by the same argument as in theorem 4.1. Theorem 4.2 survives: there is no strongly complete axiomatisation. The proof of theorem 4.5 can be adapted to show that it is not Kripke complete, using the formula

$$F(p \land G\neg p \land \neg a \land \neg b \land \Diamond a \land \Diamond b \land G(\Diamond a \land \Diamond b) \land FG\neg a) \land G(Fp \rightarrow \neg a \land \neg b).$$

The Prior axiom is no longer expressible, but a variant $Fp \land FG\neg p \rightarrow F(G\neg p \land \Diamond p)$ can be used instead.

**PROBLEM 8.4** (N. Bezhanishvili). Is the logic of $\mathbb{R}$ with connectives $G, \Box$ finitely axiomatisable?

An alternative and more expressive interpretation of $\Box$ is as ‘derivative’ $[d]$, so that $(\mathbb{R}, h), x \models [d] \varphi$ if there is an open neighbourhood $O$ of $x$ with $(\mathbb{R}, h), y \models \varphi$ for every $y \in O \setminus \{x\}$. Finite axiomatisations of the logic of $\mathbb{R}$ with $[d]$ alone (without $G, H$) and with $[d]$ and $\forall$ are given in [18] (see also Shehtman’s habilitation thesis
and [10]). Gatto [9] has recently shown that the logic of $\mathbb{R}$ in the language with $G$, $H$, and $[d]$ is finitely axiomatisable.

Other possible, non-first-order definable interpretations of $\square$ over $\mathbb{R}$ are based on cardinality and Baire category. For example, one could define $(\mathbb{R}, h), x \models \Diamond \varphi$ to hold when every open neighbourhood of $x$ contains uncountably many points $y$ with $(\mathbb{R}, h), y \models \varphi$.

**PROBLEM 8.5.** Study the logic of $\mathbb{R}$ (and, dropping $G, H$, of other topological spaces) in the language with boxes based on cardinality or Baire category, plus $G, H, \square, [d]$, and its sublanguages.

One final language consists of $G, H$ and two modalities $\square^+, \square^-$, where $(\mathbb{R}, h), x \models \square^+ \varphi$ if there is $y > x$ such that $(\mathbb{R}, h), z \models \varphi$ for every $z \in (x, y)$, and $\square^-$ is the mirror image. We could read $\square^-$ and $\square^+$ as ‘recently’ and ‘imminently’. The corresponding diamonds have been written in the literature as $K^-, K^+$, respectively.

**PROBLEM 8.6.** Find axiomatisations of the logic of $\mathbb{R}$ in this language and in sublanguages such as $\{G, \square^+\}$.
