

## C240 Computability and Complexity : Tutorial 1 Solution notes

1. The 'paradox' is that (a) the list contains all programs, so  $P = P_n$  for some  $n$ , but (b)  $P$  is written so that its output differs from  $P_n$  at the  $n$ th bit, so  $P \neq P_n$ . This is impossible, so something must be wrong with the argument. In fact the 'bug' is in line 3 – we don't know whether this line, when executed, will terminate.  $P$  may hang here forever. If  $P = P_n$ , then  $P$  may (will) hang here on the  $n$ th repeat, so  $P$  never actually prints the  $n$ th bit.
2. We know  $P = P_n$  for some  $n$ . Say  $n=19$ . To know what to output as its 19<sup>th</sup> bit,  $P$  must know the 19<sup>th</sup> bit of  $P_{19}$ 's output – ie. The 19<sup>th</sup> bit of its own output. Of course  $P$  may never get to the 19<sup>th</sup> run round the loop because maybe an earlier  $P$  (say  $P_5$ ) also happens to run forever without ever outputting 5 bits. But if it does, then on this 19<sup>th</sup> run round the loop,  $P$  will generate  $P_{19}$  – ie. A copy,  $P'$  say, of itself. It must then run this copy from the start, until it outputs 19 bits, (that's what line 3 does). But this means that  $P_{19}$  is run again up to the 19<sup>th</sup> run round the loop. Then the code of  $P'$  tells it to generate a copy of  $P_{19}$ , ie. *another* copy of  $P$ , and so on... So if  $P$  gets as far as trying to output bit 19 it goes into an infinite loop, without ever outputting again..
3. If we could write a program  $H$  such that for any  $P$ ,  $H(P) = 1$  if  $P$  halts, and  $H(P) = 0$  if  $P$  doesn't halt, we could add the lines:

2.1 if  $H(\text{"run } P_n \text{ as far as the } n\text{th bit of the output"}) = 0$  then output 1;  
next repeat; end if.

(we pass the entire text of the interpreter, plus the text of  $P_n$ , to  $H$ . We assume this halts if  $P_n$  prompts for input before outputting bit  $n$ . Now the problem in Q1 would not arise, and a real paradox results. So there is no such  $H$ .

4. Observe that if paradoxical sentence (iii) is false then you can convince yourself that it is true, so your logic is not too hot! But if it is true, you have no way of establishing that it's true – that's what it says. This shows that if your thinking never makes mistakes, (like a mathematical proof-inducer) then there are true statements whose truth you can't establish!. Cf. Gödel's incompleteness theorem. The other paradoxes are for you to lose sleep over!
