Partially Ordered Set

A partial ordering is a relation on a set L, i.e.

$$\sqsubseteq: L \times L \to \{\mathbf{t}, \mathbf{ff}\} \text{ or } \sqsubseteq L \times L$$

that is:

- $\blacktriangleright \text{ reflexive } \forall I : I \sqsubseteq I,$
- **•** transitive $\forall l_1, l_2, l_3 : l_1 \sqsubseteq l_2 \land l_2 \sqsubseteq l_3 \Rightarrow l_1 \sqsubseteq l_3$, and
- ▶ anti-symmetric $\forall I_1, I_2 : I_1 \sqsubseteq I_2 \land I_2 \sqsubseteq I_1 \Rightarrow I_1 = I_2.$

A partially ordered set (L, \sqsubseteq) is a set *L* equipped with a partial ordering \sqsubseteq (sometimes written \sqsubseteq_L). We shall write $l_2 \sqsupseteq l_1$ for $l_1 \sqsubseteq l_2$ and $l_1 \sqsubset l_2$ for $l_1 \sqsubseteq l_2 \land l_1 \neq l_2$.

Examples of POS's

Example: Integers The integers **Z** ordered in the usual way, i.e. for $i_1, i_2 \in \mathbf{Z}$:

 $i_1 \sqsubseteq i_2$ iff $i_1 \le i_2$

Example: Power-Set

Take a (finite) set X and consider at the set of all sub-sets of X, i.e. its power set $\mathcal{P}(X)$. A partial ordering on $\mathcal{P}(X)$ is given by inclusion, i.e. for two sub-sets $S_1, S_2 \in \mathcal{P}(X)$:

 $S_1 \sqsubseteq S_2$ iff $S_1 \subseteq S_2$

3/55

Upper/Lower Bounds

Given a partially ordered set (L, \sqsubseteq) .

A subset Y of L has $I \in L$ as an upper bound if

$$\forall I' \in Y : I' \sqsubseteq I$$

and as a lower bound if

$$\forall I' \in Y : I' \sqsupseteq I.$$

Least Upper/Greatest Lower Bounds

Given a partially ordered set (L, \sqsubseteq) and $Y \subseteq L$.

A least upper bound *I* of *Y* is an upper bound of *Y* that satisfies $I \subseteq I_0$ whenever I_0 is another upper bound of *Y*;

Similarly, a greatest lower bound / of Y is a lower bound of Y satisfying: $I_0 \sqsubseteq I$ whenever I_0 is another lower bound of Y.

Note that subsets *Y* of a partially ordered set *L* need not have least upper bounds nor greatest lower bounds but when they exist they are unique (since \sqsubseteq is anti-symmetric) and they are denoted $\bigsqcup Y$ and $\bigsqcup Y$, respectively.

Sometimes [] is called the *join operator* and [] the *meet operator* and we shall write $l_1 \sqcup l_2$ for $[] \{l_1, l_2\}$ and similarly $l_1 \sqcap l_2$ for $[] \{l_1, l_2\}$.

Complete Lattice

A complete lattice

$$L = (L, \sqsubseteq) = (L, \sqsubseteq, \sqcup, \sqcap, \bot, \top)$$

is a partially ordered set (L, \sqsubseteq) such that all subsets have least upper bounds as well as greatest lower bounds.

Furthermore, define $\bot = \bigsqcup \emptyset = \bigsqcup L$ is the least element and $\top = \bigsqcup \emptyset = \bigsqcup L$ is the greatest element.

Power-Set Lattice

Take a (finite) set X and look again at its power set $\mathcal{P}(X)$. A partial ordering ' \sqsubseteq ' on $\mathcal{P}(X)$ is given as above by inclusion ' \subseteq '.

The *meet* and *join* operators are given by (set) *intersection*

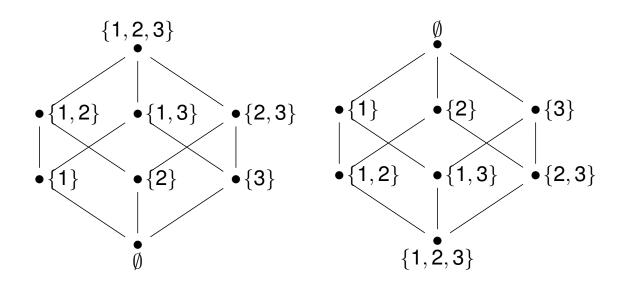

$$S_1 \sqcap S_2 = S_1 \cap S_2$$

and (set) union

 $S_1 \sqcup S_2 = S_1 \cup S_2.$

The least and greatest elements in $\mathcal{P}(X)$ are given by $\bot = \emptyset$ and $\top = X$.

Power-Set: Hasse Diagrams

Properties of Functions I

A function $f : L_1 \to L_2$ between two partially ordered sets $L_1 = (L_1, \sqsubseteq_1)$ and $L_2 = (L_2, \sqsubseteq_2)$ is *monotone* (or *isotone* or *order-preserving*) if

$$\forall I, I' \in L_1 : I \sqsubseteq_1 I' \implies f(I) \sqsubseteq_2 f(I')$$

A function $f : L_1 \rightarrow L_2$ is an *additive* function (or a *join morphism*, sometimes called a *distributive* function) if

$$\forall l_1, l_2 \in L_1 : f(l_1 \sqcup l_2) = f(l_1) \sqcup f(l_2)$$

and it is called a *multiplicative* function (or a *meet morphism*) if

$$\forall l_1, l_2 \in L_1 : f(l_1 \sqcap l_2) = f(l_1) \sqcap f(l_2)$$

Properties of Functions II

The function $f : L_1 \rightarrow L_2$ is a *completely additive* function (or a *complete join morphism*) if for all $Y \subseteq L_1$:

$$f\left(\bigsqcup_{1}Y\right) = \bigsqcup_{2}\left\{f(I') \mid I' \in Y\right\}$$
 whenever $\bigsqcup_{1}Y$ exists

and it is *completely multiplicative* (or a *complete meet morphism*) if for all $Y \subseteq L_1$:

$$f\left(\prod_{1}Y\right) = \prod_{2} \{f(I') \mid I' \in Y\}$$
 whenever $\prod_{1}Y$ exists

Cartesian Product $L_1 \times L_2$

Let $L_1 = (L_1, \sqsubseteq_1)$ and $L_2 = (L_2, \sqsubseteq_2)$ be partially ordered sets. Define $L = (L, \sqsubseteq)$ by

$$L = L_1 \times L_2 = \{ (l_1, l_2) \mid l_1 \in L_1 \land l_2 \in L_2 \}$$
$$(l_{11}, l_{21}) \sqsubseteq (l_{12}, l_{22}) \text{ iff } l_{11} \sqsubseteq_1 l_{12} \land l_{21} \sqsubseteq_2 l_{22}$$

If additionally each $L_i = (L_i, \sqsubseteq_i, \bigsqcup_i, \bigcap_i, \bot_i, \top_i)$ is a complete lattice then so is $L = (L, \sqsubseteq, \bigsqcup, \bigcap, \bot, \top)$ and furthermore

$$Y = (\ \bigsqcup_{1} \{ l_{1} \mid \exists l_{2} : (l_{1}, l_{2}) \in Y \} , \ \bigsqcup_{2} \{ l_{2} \mid \exists l_{1} : (l_{1}, l_{2}) \in Y \})$$

and $\bot = (\bot_1, \bot_2)$ and similarly for $\prod Y$ and \top .

1	1	1	5	5

Total Function Space $S \rightarrow L_1$

Let $L_1 = (L_1, \sqsubseteq_1)$ be a partially ordered set and let *S* be a set. Define $L = (L, \sqsubseteq)$ by

 $L = \{f : \mathbf{S} \to \mathbf{L}_1 \mid f \text{ is a total function} \}$ $f \sqsubseteq f' \text{ iff } \forall \mathbf{s} \in \mathbf{S} : f(\mathbf{s}) \sqsubseteq_1 f'(\mathbf{s})$

If additionally $L_1 = (L_1, \sqsubseteq_1, \bigsqcup_1, \bigcap_1, \bot_1, \top_1)$ is a complete lattice then so is $L = (L, \sqsubseteq, \bigsqcup, \bigcap, \bot, \top)$ and furthermore

$$\bigsqcup Y = \lambda s. \bigsqcup_{1} \{ f(s) \mid f \in Y \}$$

and $\bot = \lambda s . \bot_1$ and similarly for $\prod Y$ and \top .

Chains

A subset $Y \subseteq L$ of a partially ordered set $L = (L, \sqsubseteq)$ is a *chain* if

$$\forall l_1, l_2 \in Y : (l_1 \sqsubseteq l_2) \lor (l_2 \sqsubseteq l_1)$$

Thus a chain is a (possibly empty) subset of *L* that is totally ordered.

We shall say that it is a *finite chain* if it is a finite subset of *L*.

Ascending and Descending Chains

A sequence $(I_n)_n = (I_n)_{n \in \mathbb{N}}$ of elements in *L* is an *ascending chain* if

$$n \leq m \Rightarrow I_n \sqsubseteq I_m$$

Writing $(I_n)_n$ also for $\{I_n \mid n \in \mathbf{N}\}$ it is clear that an ascending chain also is a chain.

Similarly, a sequence $(I_n)_n$ is a *descending chain* if

$$n \leq m \Rightarrow I_n \sqsupseteq I_m$$

Stabilising Chains

We shall say that a sequence $(I_n)_n$ eventually stabilises if and only if

$$\exists n_0 \in \mathbf{N} : \forall n \in \mathbf{N} : n \ge n_0 \Rightarrow l_n = l_{n_0}$$

For the sequence $(I_n)_n$ we write $\bigsqcup_n I_n$ for $\bigsqcup \{I_n \mid n \in \mathbf{N}\}$ and similarly we write $\bigsqcup_n I_n$ for $\bigsqcup \{I_n \mid n \in \mathbf{N}\}$.

ACC & DCC

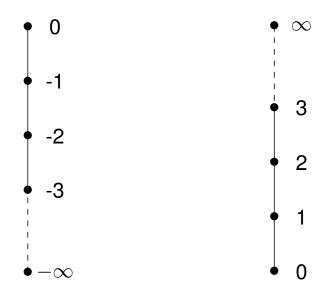

We shall say that a partially ordered set $L = (L, \sqsubseteq)$ has *finite height* if and only if all chains are finite.

It has finite height *at most h* if all chains contain at most h + 1 elements; it has finite height *h* if additionally there is a chain with h + 1 elements.

A partially ordered set *L* satisfies the *Ascending Chain Condition* (ACC) if and only if all ascending chains eventually stabilise.

A partially ordered set *L* satisfies the *Descending Chain Condition* (DCC) if and only if all descending chains eventually stabilise.

Chain Examples

Reductive and Extensive Functions Consider a monotone function $f : L \rightarrow L$ on a complete lattice *L*.

A *fixed point* of *f* is an element $I \in L$ such that f(I) = I, we write

$$Fix(f) = \{I \mid f(I) = I\}$$

for the set of fixed points.

The function f is *reductive at I* if and only if $f(I) \sqsubseteq I$ and we write

$$Red(f) = \{I \mid f(I) \sqsubseteq I\}$$

for the set of elements upon which *f* is reductive; we shall say that *f* itself is *reductive* if Red(f) = L. Similarly, the function *f* is *extensive at I* if and only if $f(I) \supseteq I$, we write

$$Ext(f) = \{I \mid f(I) \supseteq I\}$$

Fixed Points

Since *L* is a complete lattice it is always the case that the set Fix(f) will have a greatest lower bound in *L* and we denote it by Ifp(f):

$$lfp(f) = \prod Fix(f) = \prod Red(f) \in Fix(f) \subseteq Red(f)$$

Similarly, the set Fix(f) will have a least upper bound in *L* and we denote it by gfp(f):

$$gfp(f) = \bigsqcup Fix(f) = \bigsqcup Ext(f) \in Fix(f) \subseteq Ext(f)$$

19/55

Existence of Fixed Points

If *L* satisfies the Ascending Chain Condition then there exists *n* such that $f^n(\perp) = f^{n+1}(\perp)$ and hence

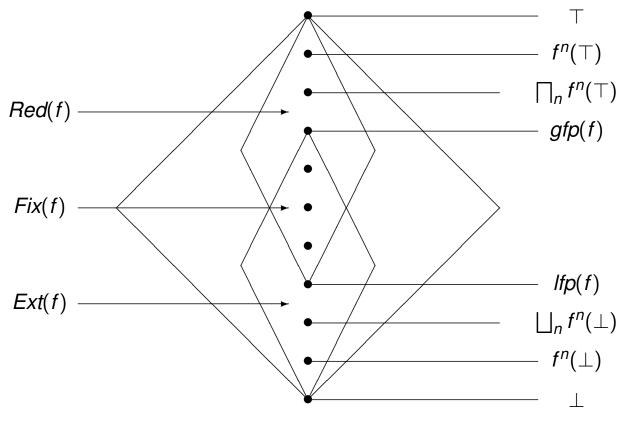

$$lfp(f) = f^n(\perp).$$

If *L* satisfies the Descending Chain Condition then there exists *n* such that $f^n(\top) = f^{n+1}(\top)$ and hence

$$gfp(f) = f^n(\top).$$

Indeed any monotone function *f* over a partially ordered set satisfying the Ascending Chain Condition is continuous.

Fix-points etc.

21/55

Fixed Points and Solutions

Given equations over some domain, e.g. integers

$$6x^3 - 3x^2 - x = 7$$

We look at it as a "recursive" equation:

$$6x^3 - 3x^2 - 7 = x$$

or simply:

$$f(x)=x.$$

If *x* is a *fixed point* of *f* then it is a *solution* to the equation.

Lattice Equations

Given a system of equations with unknowns x_1, \ldots, x_n over a complete lattice *L* (fulfilling ACC/DCC).

$$x_1 = f_1(x_1, \ldots, x_n)$$

... ...
$$x_n = f_m(x_1, \ldots, x_n)$$

Consider the equations as defining a function $F: L^n \to L^n$

$$F(x_1,\ldots,x_n)=(f_1(x_1,\ldots,x_n),\ldots,f_m(x_1,\ldots,x_n))$$

In our case we start with a recursive set of equations:

Analysis(
$$i$$
) = f_i (Analysis(1),...,Analysis(n)).

23/55

Chaotic Iteration

Iteration: Construct iteratively the smallest or largest solution/fixed point, i.e. Ifp(F) or gfp(F), by starting with

$$x_i = x_i^0 = \bot$$
 or $x_i = x_i^0 = \top$

and construct a sequence of approximations like:

$$x_i^0 = \perp$$

$$x_i^1 = f(x_1^0, \dots, x_n^0)$$

$$\dots \qquad \dots$$

$$x_i^k = f(x_1^{k-1}, \dots, x_n^{k-1})$$

until we converge, i.e. the sequence stabilises.

Look at the complete lattice $\mathcal{P}(X) = \mathcal{P}(\{a, b, c, d\})$. Construct solutions to the following set equations:

$$egin{array}{rcl} S_1 &=& \{a\}\cup S_4\ S_2 &=& S_1\cup S_3\ S_3 &=& S_4\cap\{b\}\ S_4 &=& S_2\cup\{b,c\} \end{array}$$

25/55

Two Solutions

Starting from \perp gives:

Starting from \top gives:

Knaster-Tarski Fixed Point Theorem

Mathematics literature is full of Fixed Point Theorems, e.g.

Theorem (Knaster-Tarski)

Let L be a complete lattice and assume that $f : L \mapsto L$ is an order-preserving map. Then

$$|\{x \in L \mid x \sqsubseteq f(x)\} \in Fix(f).$$

B.A. Davey and H.A. Priestley: *Introduction to Lattices and Order*, Cambridge 1990.

Classical Analyses

Each of the four classical analyses considers equations for a label consistent program S_{\star} and they take the form:

[] is \cap or \bigcup (and \sqcup is \cup or \cap), *F* is either *flow*(S_{\star}) or *flow*^{*R*}(S_{\star}), *E* is {*init*(S_{\star})} or *final*(S_{\star}), *i* specifies the initial or final analysis information, and *f*_{*l*} is the transfer function associated with $B^{\ell} \in blocks(S_{\star})$.

The forward analyses have *F* to be $flow(S_*)$ and then *Analysis*_o concerns entry conditions and *Analysis*_o concerns exit conditions; also the equation system presupposes that S_* has isolated entries.

The backward analyses have *F* to be $flow^R(S_*)$ and then *Analysis*_o concerns exit conditions and *Analysis*_o concerns entry conditions; also the equation system presupposes that S_* has isolated exits.

Must vs May Analysis

When $[\]$ is \cap we require the *greatest* sets that solve the equations and we are able to detect properties satisfied by *all* paths of execution reaching (or leaving) the entry (or exit) of a label; these analyses are often called must analyses.

When $[\]$ is $[\]$ we require the *least* sets that solve the equations and we are able to detect properties satisfied by *at least one* execution path to (or from) the entry (or exit) of a label; these analyses are often called may analyses.

Alternative Formulation

It is occasionally awkward to have to assume that forward analyses have isolated entries and that backward analyses have isolated exits. This motivates reformulating the above equations to be of the form:

$$\begin{aligned} \text{Analysis}_{\circ}(\ell) &= \bigsqcup \{\text{Analysis}_{\bullet}(\ell') \mid (\ell', \ell) \in F\} \sqcup \iota_{E}^{\ell} \\ \text{Analysis}_{\bullet}(\ell) &= f_{\ell}(\text{Analysis}_{\circ}(\ell)) \end{aligned}$$

where

$$\iota_E^\ell = \left\{ egin{array}{cc} \iota & ext{if } \ell \in E \ ot & ot & ext{if } \ell \notin E \end{array}
ight.$$

and \perp satisfies $I \sqcup \perp = I$ (hence \perp is not really there).

31/55

Transfer Functions

The view that we take here is that a program is a *transition system*; the nodes represent blocks and each block has a transfer function associated with it that specifies how the block acts on the "input" state.

Note that for forward analyses, the input state is the entry state, and for backward analyses, it is the exit state.

Monotone & Distributive Frameworks

A Monotone Framework consists of:

- ► a complete lattice, L, that satisfies the Ascending Chain Condition, and we write [] for the least upper bound operator; and
- a set F of monotone functions from L to L that contains the identity function and that is closed under function composition.

A Distributive Framework is a Monotone Framework where additionally all functions f in \mathcal{F} are required to be distributive:

$$f(I_1 \sqcup I_2) = f(I_1) \sqcup f(I_2)$$

Instance of a Framework

An *instance*, Analysis, of a Monotone or Distributive Framework to consists of:

- ► the complete lattice, *L*, of the framework;
- the space of transfer functions, \mathcal{F} , of the framework;
- ▶ a finite flow, *F*, that typically is $flow(S_{\star})$ or $flow^{R}(S_{\star})$;
- a finite set of so-called extremal labels, *E*, that typically is {*init*(*S*_{*})} or *final*(*S*_{*});
- ▶ an extremal value, $\iota \in L$, for the extremal labels; and
- a mapping, f., from the labels Lab_{*} of F to transfer functions in F.

An instance gives rise to a *set of equations*, Analysis⁼, of the form considered earlier:

$$\begin{aligned} \text{Analysis}_{\circ}(\ell) &= \bigsqcup \{\text{Analysis}_{\bullet}(\ell') \mid (\ell', \ell) \in F\} \sqcup \iota_{E}^{\ell} \\ \text{where } \iota_{E}^{\ell} &= \begin{cases} \iota & \text{if } \ell \in E \\ \bot & \text{if } \ell \notin E \end{cases} \end{aligned}$$
$$\begin{aligned} \text{Analysis}_{\bullet}(\ell) &= f_{\ell}(\text{Analysis}_{\circ}(\ell)) \end{aligned}$$

35/55

Classical Instances

	Available	Reaching	Very Busy	Live		
	Expressions	Definitions	Expressions	Variables		
L	$\mathcal{P}(AExp_{\star})$	$\mathcal{P}(Var_\star imes Lab_\star)$	$\mathcal{P}(AExp_{\star})$	$\mathcal{P}(Var_{\star})$		
	\supseteq	\subseteq	\supseteq	\subseteq		
	\cap	U	\cap	U		
\perp	AExp _*	Ø	AExp _*	Ø		
ι	Ø	$\{(x,?) x \in FV(S_{\star})\}$	Ø	Ø		
Ε	$\{init(S_{\star})\}$	$\{init(S_{\star})\}$	final(S_{\star})	final(S_{\star})		
F	flow(S_{\star})	$\mathit{flow}(S_\star)$	$\mathit{flow}^R(S_\star)$	$flow^R(S_{\star})$		
\mathcal{F}	$\{f: L \to L \mid \exists I_k, I_g: f(I) = (I \setminus I_k) \cup I_g\}$					
f_ℓ	$f_\ell(I) = (I \setminus kill([B]^\ell)) \cup gen([B]^\ell)$ where $[B]^\ell \in blocks(S_\star)$					

Classical Monotone Frameworks

Lemma: Each of the four classical data flow analyses is a Monotone Framework as well as a Distributive Framework.

It is worth pointing out that in order to get this result we have made the frameworks dependent upon the actual program – this is needed to enforce that the Ascending Chain Condition is fulfilled.

A Non-Distributive Example

The Constant Propagation Analysis (CP) will determine:

For each program point, whether or not a variable has a constant value whenever execution reaches that point.

Such information can be used as the basis for an optimisation known as *Constant Folding*: all uses of the variable may be replaced by the constant value.

CP State: \mathbf{Z}^{\top}

The (abstract) states for the CP Analysis are given by:

$$\widehat{\mathsf{State}}_{\mathsf{CP}} = ((\mathsf{Var}_{\star} \to \mathsf{Z}^{\top})_{\perp}, \sqsubseteq, \sqcup, \sqcap, \bot, \lambda x. \top)$$

where Var_{\star} is the set of variables appearing in the program.

 $\mathbf{Z}^{\top} = \mathbf{Z} \cup \{\top\}$ is partially ordered as follows:

$$\forall z \in \mathbf{Z}^\top : z \sqsubseteq \top$$
$$\forall z_1, z_2 \in \mathbf{Z} : (z_1 \sqsubseteq z_2) \Leftrightarrow (z_1 = z_2)$$

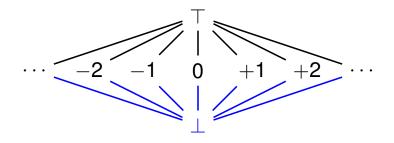

39/55

CP State: Partial Order \mathbf{Z}^{\top} vs Lattice $\mathbf{Z}_{\perp}^{\top}$

We construct a non-standard partial order on Z:

We could also consider a complete lattice $\mathbf{Z}_{\perp}^{\top}$ (but don't):

CP State: Lattice

To capture the case where no information is available we extend $Var_{\star} \rightarrow Z^{\top}$ with a least element \bot , written $(Var_{\star} \rightarrow Z^{\top})_{\bot}$.

The partial ordering \sqsubseteq on $\widehat{\text{State}}_{CP} = (\text{Var}_{\star} \rightarrow \textbf{Z}^{\top})_{\perp}$ is:

$$\begin{aligned} \forall \widehat{\sigma} \in (\mathsf{Var}_{\star} \to \mathsf{Z}^{\top})_{\perp} : \quad \bot \sqsubseteq \widehat{\sigma} \\ \forall \widehat{\sigma}_{1}, \widehat{\sigma}_{2} \in \mathsf{Var}_{\star} \to \mathsf{Z}^{\top} : \quad \widehat{\sigma}_{1} \sqsubseteq \widehat{\sigma}_{2} \quad \text{iff} \ \forall x : \widehat{\sigma}_{1}(x) \sqsubseteq \widehat{\sigma}_{2}(x) \end{aligned}$$

and the binary least upper bound operation is then:

$$\forall \widehat{\sigma} \in (\mathsf{Var}_{\star} \to \mathsf{Z}^{\top})_{\perp} : \quad \widehat{\sigma} \sqcup \bot = \widehat{\sigma} = \bot \sqcup \widehat{\sigma}$$
$$\forall \widehat{\sigma}_{1}, \widehat{\sigma}_{2} \in \mathsf{Var}_{\star} \to \mathsf{Z}^{\top} : \quad \forall x : (\widehat{\sigma}_{1} \sqcup \widehat{\sigma}_{2})(x) = \widehat{\sigma}_{1}(x) \sqcup \widehat{\sigma}_{2}(x)$$

41/55

CP State Evaluation

$$\mathcal{A}_{\mathsf{CP}} : \operatorname{\mathsf{AExp}} \to (\widehat{\operatorname{State}}_{\mathsf{CP}} \to \mathbf{Z}_{\perp}^{\top})$$

$$\mathcal{A}_{\mathsf{CP}}\llbracket x \rrbracket \widehat{\sigma} = \begin{cases} \bot & \text{if } \widehat{\sigma} = \bot \\ \widehat{\sigma}(x) & \text{otherwise} \end{cases}$$

$$\mathcal{A}_{\mathsf{CP}}\llbracket n \rrbracket \widehat{\sigma} = \begin{cases} \bot & \text{if } \widehat{\sigma} = \bot \\ n & \text{otherwise} \end{cases}$$

$$\mathcal{A}_{\mathsf{CP}}\llbracket a_1 \, op_a \, a_2 \rrbracket \widehat{\sigma} = \mathcal{A}_{\mathsf{CP}}\llbracket a_1 \rrbracket \widehat{\sigma} \, \widehat{\mathsf{op}}_a \, \mathcal{A}_{\mathsf{CP}}\llbracket a_2 \rrbracket \widehat{\sigma}$$

The operations on **Z** are lifted to $\mathbf{Z}_{\perp}^{\top} = \mathbf{Z} \cup \{\perp, \top\}$ by taking $z_1 \ \widehat{\text{op}}_a \ z_2 = z_1 \ \mathbf{op}_a \ z_2$ if $z_1, z_2 \in \mathbf{Z}$ (and where \mathbf{op}_a is the corresponding arithmetic operation on **Z**), $z_1 \ \widehat{\text{op}}_a \ z_2 = \perp$ if $z_1 = \perp$ or $z_2 = \perp$ and $z_1 \ \widehat{\text{op}}_a \ z_2 = \top$ otherwise.

CP Transfer Function

 $\mathcal{F}_{CP} = \{f \mid f \text{ is a monotone function on } \widehat{\mathbf{State}}_{CP}\}$

$$\begin{split} [\mathbf{x} := \mathbf{a}]^{\ell} : & f_{\ell}^{\mathsf{CP}}(\widehat{\sigma}) = \begin{cases} \bot & \text{if } \widehat{\sigma} = \bot \\ \widehat{\sigma}[\mathbf{x} \mapsto \mathcal{A}_{\mathsf{CP}}[\![\mathbf{a}]\!]\widehat{\sigma}] & \text{otherwise} \end{cases} \\ [\mathbf{skip}]^{\ell} : & f_{\ell}^{\mathsf{CP}}(\widehat{\sigma}) = \widehat{\sigma} \\ [\mathbf{b}]^{\ell} : & f_{\ell}^{\mathsf{CP}}(\widehat{\sigma}) = \widehat{\sigma} \end{cases}$$

43/55

CP Flow

Constant Propagation (CP) is a forward analysis, so for the program S_* we take the flow, F, to be $flow(S_*)$.

The extremal labels, *E*, are given by $\{init(S_*)\}$, and the extremal value, ι_{CP} , is $\lambda x. \top$. The property lattice *L* and transfer function \mathcal{F}_{CP} as above.

Lemma: Constant Propagation is a Monotone Framework that is *not* a Distributive Framework.

Distributive Framework

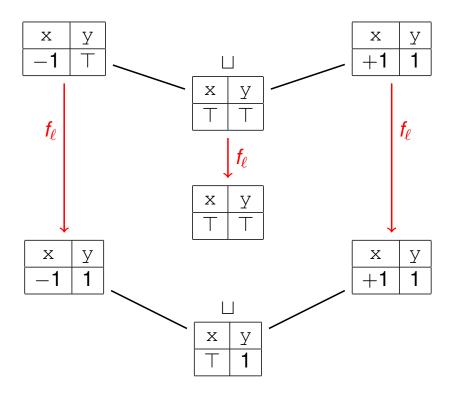

To show that it is not a Distributive Framework consider the transfer function f_{ℓ}^{CP} for $[\mathbf{y} := \mathbf{x} * \mathbf{x}]^{\ell}$ and let $\hat{\sigma}_1$ and $\hat{\sigma}_2$ be such that $\hat{\sigma}_1(\mathbf{x}) = 1$ and $\hat{\sigma}_2(\mathbf{x}) = -1$.

Then $\widehat{\sigma}_1 \sqcup \widehat{\sigma}_2$ maps x to \top and thus $f_{\ell}^{CP}(\widehat{\sigma}_1 \sqcup \widehat{\sigma}_2)$ maps y to \top and hence fails to record that y has the constant value 1.

However, both $f_{\ell}^{CP}(\widehat{\sigma}_1)$ and $f_{\ell}^{CP}(\widehat{\sigma}_2)$ map y to 1 and so does $f_{\ell}^{CP}(\widehat{\sigma}_1) \sqcup f_{\ell}^{CP}(\widehat{\sigma}_2)$.

Transfer Functions and Information Collection

Consider transfer function for the block $[y := x * x]^{\ell}$.

The MFP Solution (1)

- INPUT: An instance of a Monotone Framework: $(L, \mathcal{F}, F, E, \iota, f)$
- OUTPUT: *MFP*_o, *MFP*_•

Step 1: Initialisation (of W and Analysis) W := nil; for all (ℓ, ℓ') in F do W := cons $((\ell, \ell'), W)$; for all ℓ in F or E do if $\ell \in E$ then Analysis $[\ell] := \iota$ else Analysis $[\ell] := \bot_L$;

The MFP Solution (2&3)

Step 2: Iteration (updating W and Analysis) while $W \neq nil do$ $\ell := fst(head(W)); \ell' = snd(head(W));$ W := tail(W);if $f_{\ell}(Analysis[\ell]) \not\sqsubseteq Analysis[\ell']$ then Analysis $[\ell'] := Analysis[\ell'] \sqcup f_{\ell}(Analysis[\ell]);$ for all (ℓ', ℓ'') in F do $W := cons((\ell', \ell''), W);$ Step 3: Presenting the result (MFP_{\circ} and MFP_{\bullet}) for all ℓ in F or E do $MFP_{\circ}(\ell) := Analysis[\ell];$ $MFP_{\bullet}(\ell) := f_{\ell}(Analysis[\ell])$ 47/55

MFP Termination

Given an instance of a Monotone Framework $(L, \mathcal{F}, F, E, \iota, f)$ with a property lattice *L* fullfilling the ACC/DCC.

Starting from \perp and using iterative (approximation) methods like Chaotic Iteration or the Worklist Algorithm (which optimses the iterations by only considering updates when "necessary") we can compute solutions *Analysis*_o and *Analysis*_o.

Lemma: The iterative construction of a solution (using chaotic iteration, worklist algorithm) always terminates and it computes the least MFP solution (more precisely MFP_{\circ} and MFP_{\bullet}) to the instance of the framework.

MFP Complexity

Assume that the flow *F* is represented in such a way that all (ℓ', ℓ'') emanating from ℓ' can be found in time proportional to their number. Suppose that *E* and *F* contain at most $b \ge 1$ distinct labels, that *F* contains at most $e \ge b$ pairs, and that *L* has finite height at most $h \ge 1$.

Then steps 1 and 3 perform at most O(b + e) basic operations. In step 2 a pair is placed on the worklist at most O(h) times, and each time it takes only a constant number of basic steps to process it; this yields at most $O(e \cdot h)$ basic operations for step 2. Since $h \ge 1$ and $e \ge b$ this gives at most $O(e \cdot h)$ basic operations for the algorithm.

RD Complexity

Consider the Reaching Definitions Analysis and suppose that there are at most $v \ge 1$ variables and $b \ge 1$ labels in the program, S_* , being analysed. Since $L = \mathcal{P}(\text{Var}_* \times \text{Lab}_*)$, it follows that $h \le v \cdot b$ and thus we have an $O(v \cdot b^3)$ upper bound on the number of basic operations.

Better: If S_* is label consistent then the variable of the pairs (x, ℓ) of $\mathcal{P}(\operatorname{Var}_* \times \operatorname{Lab}_*)$ will always be uniquely determined by the label ℓ so we get an $O(b^3)$ upper bound on the number of basic operations. Furthermore, *F* is $flow(S_*)$ and inspection of the equations for $flow(S_*)$ shows that for each label ℓ we construct at most two pairs with ℓ in the first component. This means that $e \leq 2 \cdot b$ and we get an $O(b^2)$ upper bound on the number of number of basic operations.

MOP Solution: Paths

Consider an instance $(L, \mathcal{F}, F, E, \iota, f)$ of a Monotone Framework.

We shall use the notation $\vec{\ell} = [\ell_1, \cdots, \ell_n]$ for a sequence of $n \ge 0$ labels.

The paths up to *but not* including ℓ are:

 $path_{\circ}(\ell) = \{ [\ell_1, \cdots, \ell_{n-1}] \mid n \ge 1 \land \forall i < n : (\ell_i, \ell_{i+1}) \in F \land \ell_n = \ell \land \ell_1 \in E \}$

The paths up to *and* including ℓ are:

 $path_{\bullet}(\ell) = \{ [\ell_1, \cdots, \ell_n] \mid n \ge 1 \land \forall i < n : (\ell_i, \ell_{i+1}) \in F \land \ell_n = \ell \land \ell_1 \in E \}$

MOP Solutions

For a path $\vec{\ell} = [\ell_1, \cdots, \ell_n]$ we define the transfer function

$$f_{\vec{\ell}} = f_{\ell_n} \circ \cdots \circ f_{\ell_1} \circ id$$

so that for the empty path we have $f_{[]} = id$ where *id* is the identity function.

The MOP solutions are then given by:

$$MOP_{\circ}(\ell) = \bigsqcup \{ f_{\vec{\ell}}(\iota) \mid \vec{\ell} \in path_{\circ}(\ell) \}$$
$$MOP_{\bullet}(\ell) = \bigsqcup \{ f_{\vec{\ell}}(\iota) \mid \vec{\ell} \in path_{\bullet}(\ell) \}$$

MOP Solution: Termination

Unfortunately, the MOP solution sometimes cannot be computable (meaning that it is undecidable what the solution is) even though the MFP solution is always easily computable (because of the property space satisfying the Ascending Chain Condition); the following result establishes one such result:

Lemma: The MOP solution for the Constant Propagation Analysis is undecidable.

MFP and MOP Solutions

Lemma: Consider the MFP and the MOP solutions to an instance $(L, \mathcal{F}, F, B, \iota, f)$ of a Monotone Framework; then:

$$MFP_{\circ} \supseteq MOP_{\circ}$$
 and $MFP_{\bullet} \supseteq MOP_{\bullet}$

If the framework is a Distributive Framework and if $path_{\circ}(\ell) \neq \emptyset$ for all ℓ in *E* and *F* then:

 $MFP_{\circ} = MOP_{\circ}$ and $MFP_{\bullet} = MOP_{\bullet}$

It is always possible to formulate the MOP solution as an MFP solution over a different property space (like $\mathcal{P}(L)$) and therefore little is lost by focusing on the fixed point approach to Monotone Frameworks.
