Iterative Learning of Answer Set Programs from Context Dependent Examples

Mark Law, Alessandra Russo and Krysia Broda

September 4, 2016

(a)

Context-dependent examples

▶ In standard ILP, we search for hypotheses *H* such that:

- ▶ $\forall e \in E^+ \ B \cup H \models e$
- ► $\forall e \in E^- \ B \cup H \not\models e$

Given context-dependent examples, it must be the case that:

◆□ ▶ ◆圖 ▶ ◆ 圖 ▶ ◆ 圖 ▶ …

э.

$$\blacktriangleright \ \forall \langle e, C \rangle \in E^+ \ B \cup H \cup C \models e$$

$$\blacktriangleright \ \forall \langle e, C \rangle \in E^- \ B \cup H \cup C \not\models e.$$

Context-dependent examples

▶ In standard ILP, we search for hypotheses *H* such that:

- $\blacktriangleright \forall e \in E^+ \ B \cup H \models e$
- ► $\forall e \in E^- \ B \cup H \not\models e$

Given context-dependent examples, it must be the case that:

- $\forall \langle e, C \rangle \in E^+ \ B \cup H \cup C \models e$
- $\blacktriangleright \quad \forall \langle e, C \rangle \in E^- \ B \cup H \cup C \not\models e.$

For example, we may wish to learn that when it is raining a user prefers to take the bus; otherwise, they prefer to walk.

$$\mathsf{E}^{+} = \left\{ \begin{array}{ll} \langle \text{``take bus''}, \{\texttt{rain.}\} \rangle, \\ \langle \text{``walk''}, \{\} \rangle \end{array} \right. \mathsf{E}^{-} = \left\{ \begin{array}{ll} \langle \text{``walk''}, \{\texttt{rain.}\} \rangle, \\ \langle \text{``take bus''}, \{\} \rangle \end{array} \right.$$

Learning from Answer Sets (ILP_{LAS})

- In ILP_{LAS} (Law et al. 2014), examples are partial interpretations.
- ► A partial interpretation *e* is a set of pairs of atoms $\langle e^{inc}, e^{exc} \rangle$.

$$\left\langle \left\{ \begin{array}{c} \text{size(4)} \\ \text{edge(1,2)} \\ \text{edge(2,3)} \\ \text{edge(3,4)} \\ \text{edge(4,1)} \end{array} \right\}, \left\{ \begin{array}{c} \text{edge(1,1)} \\ \text{edge(1,3)} \\ \text{edge(1,4)} \\ \dots \end{array} \right\} \right\rangle$$

э

$$O^{b} = \left\{ \begin{array}{c} \langle e_{1}, e_{2} \rangle \\ & \ddots \end{array} \right\}$$

Complexity

► In the paper, we present a mapping T_{LOAS} from any ILP^{context}_{LOAS} task to an ILP_{LOAS} task.

Theorem 1

For any $ILP_{LOAS}^{context}$ task T, $ILP_{LOAS}(\mathcal{T}_{LOAS}(T)) = ILP_{LOAS}^{context}(T)$.

Theorem 2

The complexity of deciding whether an $ILP_{LOAS}^{context}$ task is satisfiable is Σ_2^P -complete.

< □ > < @ > < E > < E > E の < @ 8/12

ILASP2i

- ► The mapping *T_{LOAS}* means that we can use ILASP2 to compute solutions for any context dependent task:
 - This would be by calling $ILASP2(\mathcal{T}_{LOAS}(\langle B, S_M, E \rangle))$.
 - However, ILASP2 is known to scale poorly wrt the number of examples.
- Our new algorithm, ILASP2i, iteratively computes a subset of the examples *Rel*, called *relevant examples*.
 - ▶ In each iteration, we call $ILASP2(\mathcal{T}_{LOAS}(\langle B, S_M, Rel \rangle))$.

Theorem 4

ILASP2i is sound for any well defined ILP^{context} task, and returns an optimal solution if one exists.

Benchmarks

Learning	#examples			tim	e/s	Memory/kB		
task	E^+	E^{-}	O^b	O^{c}	2	2i	2	2i
Hamilton A (no context)	100	100	0	0	10.3	4.3	9.7×10^4	1.2×10 ⁴
Hamilton B (context dep.)	100	100	0	0	32.0	3.6	3.6×10^{5}	$1.4\!\times\!10^4$
Journeys (context dep.)	386	0	200	0	1031.4	5.0	1.4×10^{7}	3.4×10 ⁴

- ILASP2 runs the automatic translation (*T_{LOAS}*) of context dependent tasks.
- ► *T_{LOAS}*(Hamilton B) is less efficient than Hamilton A.
- ► T_{LOAS}(Journeys) is the same as the non-context dependent Journey task.

Context-dependent examples

▶ In standard ILP, we search for hypotheses *H* such that:

- ▶ $\forall e \in E^+ \ B \cup H \models e$
- ► $\forall e \in E^- \ B \cup H \not\models e$

Given context-dependent examples, it must be the case that:

$$\blacktriangleright \quad \forall \langle e, C \rangle \in E^+ \ B \cup H \cup C \models e$$

 $\blacktriangleright \quad \forall \langle e, C \rangle \in E^- \ B \cup H \cup C \not\models e.$

For example, we may wish to learn that when it is raining a user prefers to take the bus; otherwise, they prefer to walk.

$$E^{+} = \begin{cases} \langle \text{``take bus''}, \{1\{\texttt{rain}, \texttt{snow}\}1.\} \rangle, \\ \langle \text{``walk''}, \{\} \rangle \\ E^{-} = \begin{cases} \langle \text{``walk''}, \{\texttt{rain.}\} \rangle, \\ \langle \text{``take bus''}, \{\} \rangle \end{cases} \end{cases}$$
