# DeepLogic: Towards End-to-End Differentiable Logical Reasoning

using Neural Memory Networks

Nuri C.

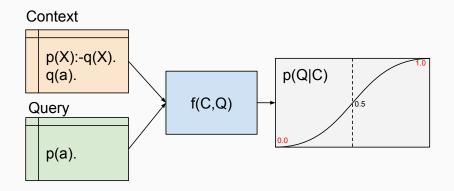

March 2019

Imperial College London

Deep learning [1] learns human level tasks. Logic [2] formalises reasoning. Deep learn to reason logically ?

- 1. If and how neural networks learn to represent symbolic constructs from logic?
- 2. If and how iterative neural networks use those representations to perform reasoning over logic programs?

Setup

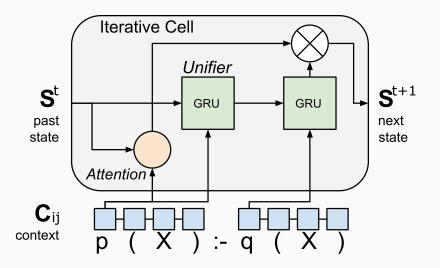

- 12 tasks each with 20k training and 10k validation, 10k test.
- Normal logic programs with negated atoms and positive atoms as literals, synthetically generated.
- No function applications or recursion allowed.
- Upper case English alphabet for variables, lower case for predicates *and* constants, ex. p(X),p(q),q(p).
- Ground atoms as queries, ex. p(a).
- Maximum arity 2.

 Table 1: Sample programs from tasks 9 to 12.

- Training predicates and constants up to 2 characters, longer for test sets. 4, 8 and 12 characters and irrelevant rules for easy, medium and hard sets respectively.
- Training up to 3 hops, longer for multi-hop analysis test (up to 32 hops).
- Publicly available online with generation script, https://github.com/nuric/deeplogic

# **Attention Visualisation**

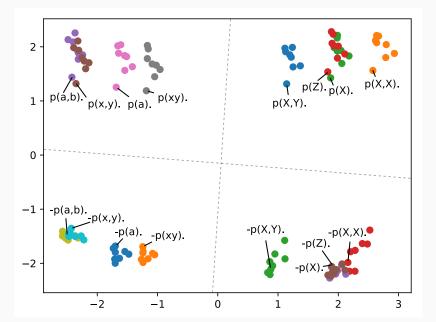

**Figure 1:** Attention maps produced for query p(a) for IMA with softmax attention performing *backward* chaining in the left column and IMA with literal + rule embedding *forward* chaining in the right column on tasks 5 to 7.

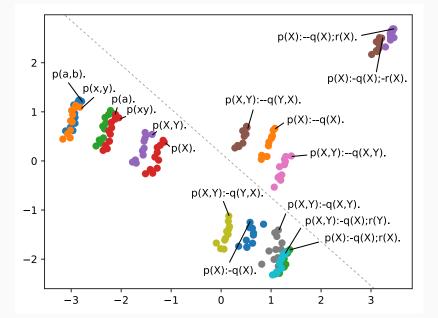

## Literal Embedding Visualisation

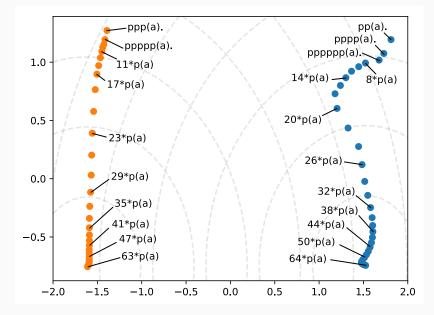

## Structurally Different Literals

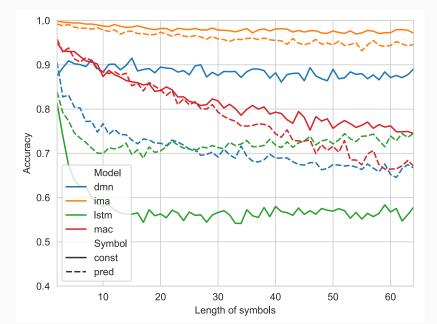

#### Structurally Different Rules

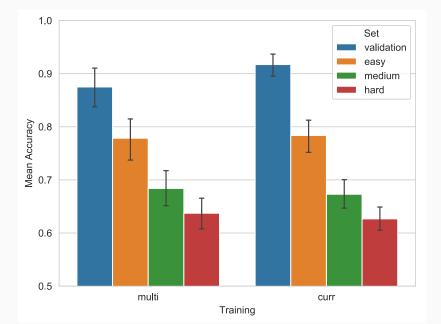

## Literal Embedding Saturation

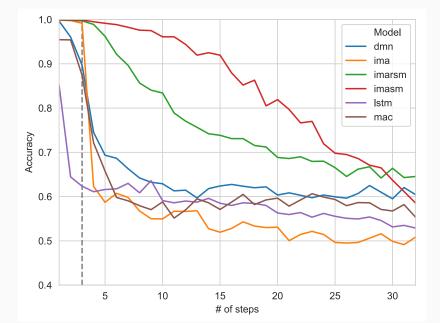

## Increasing Symbol Lengths

Training Regime

# Multi-hop Reasoning

# **Concluding Remarks**

- Embedding space attempts to uniquely represent symbolic entities, clustered by structural similarity.
- Negation is learnt as separate representation if forced into same embedding space.
- No backtracking, instead attend to multiple rules at the same iteration step, potentially solving in fewer steps.
- Incrementally training on tasks have no advantage despite logically sharing constructs.
- Iterative applications, re-usage and updating of state vector seem to degrade performance over multiple iterations.

# Questions

#### Iteration

$$ca_{i}^{t} = [s^{t}; q; r_{i}; (s^{t} - r_{i})^{2}; s^{t} \odot r_{i}]$$
 (1)

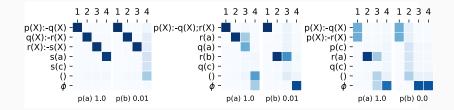

$$\alpha_{i}^{t} = \sigma(W^{1 \times \frac{d}{2}}(U^{\frac{d}{2} \times d}ca_{i}^{t} + b^{\frac{d}{2}}) + b^{1})$$
(2)

$$u_{ij}^t = GRU(\mathbf{C}_{ij}, u_{i(j-1)}^t)$$
(3)

$$s^{t+1} = \sum_{i}^{R} \alpha_{i}^{t} u_{iL}^{t} \tag{4}$$

We kick start the process by setting the initial state to the query  $s^0 = q$ . At every iteration compute features between the current state and the rules  $ca_i^t$  to capture which rules are relevant. With initial hidden state  $u_{i0}^t = s^t$ , compute interaction between state and rule  $u_{ii}^t$ , perform weighted sum to get next state  $s^{t+1}$ .
